AT THE UNIVERSITY PRESS

## PREFACE.

In the present Treatise the Conic Sections are defined with reference to a focus and directrix, and I have endeavoured to place before the student the most important properties of those curves, deduced, as closely as possible, from the definition.

The construction which is given in the first Chapter for the determination of points in a conic section possesses several advantages ; in particular, it leads at once to the constancy of the ratio of the square on the ordinate to the rectangle under its distances from the vertices ; and, again, in the case of the hyperbola, the directions of the asymptotes follow immediately from the construction. In several cases the methods employed are the same as those of Wallace, in the Treatise on Conic Sections, published in the Encyclopadia Metropolitana.

The deduction of the properties of these curves from their definition as the sections of a cone, seems a priori to be the natural method of dealing with the subject, but experience appears to have shewn that
the discussion of conics as defined by their plane properties is the most suitable method of commencing an elementary treatise, and accordingly I follow the fashion of the time in taking that order for the treatment of the subject. In Hamilton's book on Conic Sections, published in the middle of the last century, the properties of the cone are first considered, and the advantage of this method of commencing the subject, if the use of solid figures be not objected to, is especially shewn in the very general theorem of Art. (150). I have made much use of this treatise, and, in fact, it contains most of the theorems and problems which are now regarded as classical propositions in the theory of Conic Sections.

I have considered first, in Chapter I., a few simple properties of conics, and have then proceeded to the particular properties of each curve, commencing with the parabola, as in some respects, the simplest form of a conic section.

It is then shewn, in Chapter VI., that the sections of a cone. by a plane produce the several curves in question, and lead at once to their definition as loci, and to several of their most important properties.

A chapter is devoted to the method of orthogonal projection, and another to the harmonic properties of curves, and to the relations of poles and polars.
including the theory of reciprocal polars for the particular case in which the circle is employed as the auxiliary curve.

For the more general methods of projections, of reciprocation, and of anharmonic properties, the student will consult the treatises of Chasles, Poncelet, Salmon, Townsend, Ferrers, Whitworth, and others, who have recently developed, with so much fulness, the methods of modern Geometry.

I have to express my thanks to Mr R. B. Worthington, of St John's College, and of the Indian Civil Service, for valuable assistance in the constructions of Chapter XI., and also to Mr E. Hill, Fellow of St John's College, for his kindness in looking over the latter half of the proof-sheets.

I venture to hope that the methods adopted in this treatise will give a clear view of the properties of Conic Sections, and that the numerous Examples appended to the various Chapters will be useful as an exercise to the student for the further extension of his conceptions of these curves.

W. H. BESANT.

Cambridge,
March, 1869.

## PREFACE TO THE FOURTH EDITION.

For this edition the text has been carefully revised, some redundant examples have been removed, and fresh examples, taken chiefly from recent examination papers, have been inserted.

A book of Solutions of the Examples has been prepared, in accordance with requests which have been received from many teachers, and will be issued with the present edition.

## W. H. BESANT.

Sept. 1881.

## PREFACE TO THE EIGHTH EDITION.

For this edition some slight alterations have been made, and some additional examples inserted.

The Book of Solutions of the Examples has been also revised, and has been made to be in complete accordance with the present edition.

W. H. BESANT.

March, 1890.

## CONIC SECTIONS.

## INTRODUCTION.

DEFINITION.

IF a straight line and a point be given in position in a plane, and if a point move in a plane in such a manner that its distance from the given point always bears the same ratio to its distance from the given line, the curve traced out by the moving point is called a Conic Section.

The fixed point is called the Focus, and the fixed line the Directrix of the conic section.

When the ratio is one of equality, the curve is called a Parabola.

When the ratio is one of less inequality, the curve is called an Ellipse.

When the ratio is one of greater inequality, the curve is called an Hyperbola.

These curves are called Conic Sections, because they can all be obtained from the intersections of a Cone by planes in different directions, a fact which will be proved hereafter.

It may be mentioned that a circle is a particular case of an ellipse, that two straight lines coustitute a particular
case of an hyperknia, and that a parabola may be looked upon as the limiting form of an ellipse or an hyperbola, under certain conditions of variation in the lines and magnitudes upon which those curves depend for their form.

The object of the following pages is to discuss the general forms and characters of these curves, and to determine their most important properties by help of the methods and relations developed in the first six books, and in the eleventh book of Euclid, and it will be found that, for this purpose, a knowledge of Euclid's Geometry is all that is necessary.

The series of demonstrations will shew the characters and properties which the curves possess in common, and also the special characteristics wherein they differ from each other; and the continuity with which the curves pass into each other will appear from the definition of a conic section as a Locus, or curve traced out by a moving point, as well as from the fact that they are deducible from the intersections of a cone by a succession of planes.

## CHAPTER I.

## PROPOSITION 1.

The Construction of a Conic Section.

1. TAKE $S$ as the focus, and from $S$ draw $S X$ at right angles to the directrix, and intersecting it in the point $X$.

Definttion. This line $S X$, produced both ways, is called the Axis of the Conic Section.

In $S X$ take a point $A$ such that the ratio of $S A$ to $A X$ is equal to the given ratio ; then $A$ is a point in the curve.

Def. The point $A$ is called the Vertex of the curve.
In the directrix $E X$ take any point $E$, join $E A$, and $E S$, produce these lines, and through $S$ draw the straight

line $S Q$ making with $E S$ produced the same angle which $E S$ produced makes with the axis $S N$.

Let $P$ be the point of intersection of $S Q$ and $E A$ produced, and through $P$ draw $L P K$ parallel to $N X$, and intersecting $E S$ produced in $L$, and the directrix in $K$.

Then the angle $P L S$ is equal to the angle $L S N$ and therefore to $P S L$;

Hence

$$
S P=P L
$$

Also

$$
\begin{aligned}
& P L: A S:: E P: E A \\
& \text { :: } P K \text { : } A X \text {; } \\
& \therefore P L: P K:: A S: A X ; \\
& \therefore S P: P K:: A S: A X \text {. }
\end{aligned}
$$

and
The point $P$ is therefore a point in the curve required, and by taking for $E$ successive positions along the directrix we shall, by this construction, obtain a succession of points in the curve.

If $E$ be taken on the upper side of the axis at the same distance from $X$, it is easy to see that a point $P$ will be obtained below the axis, which will be similarly situated with regard to the focus and directrix. Hence it follows that the axis divides the curve into two similar and equal portions.

Another point of the curve, lying in the straight line $K P$, can be found in the following manner.

Through $S$ draw the straight line $F S$ making the angle $F S K$ equal to $K S P$, and let $F S$ produced meet $K P$ produced in $P^{\prime}$.

Then, since $K S$ bisects the angle $P S F$,

$$
\begin{aligned}
S P & : S P \\
\therefore S P^{\prime} & : P^{\prime} K
\end{aligned}:: S P \text { : } P P,
$$

and $P^{\prime}$ is a point in the curve.
2. Def. The Eccentricity. The constant ratio of the distance from the focus of any point in a conic section to its distance from the directrix is called the eccentricity of the conic section.

The Latus Rectum. If $E$ be so taken that $E X$ is equal to $S X$, the angle $P S N$, which is double the angle $L S N$, and therefore double the angle $E S X$, is a right angle.

For, since $E X=S X$, the angle $E S X=S E X$, and, the angle $S X E$ being a right angle, the sum of the two angles SEX, ESX, which is equal to twice $E S X$, is also equal to a right angle.

Calling $R$ the position of $P$ in this case, produce $R S$ to $R^{\prime}$, so that $R^{\prime} S=R S$; then $R^{\prime}$ is also a point in the curve.

DeF. The straight line RSR' drawn through the focus at right angles to the axis, and intersecting the curve in $R$ and $R^{\prime}$, is called the Latus Rectum.

It is hence evident that the form of a conic section is determined by its eccentricity, and that its magnitude is determined by the magnitude of the Latus Rectum, which is given by the relation

$$
S R: S X:: S A: A X
$$

3. Def. The straight line $P N$ (Fig. Art. 1), drawn from any point $P$ of the curve at right angles to the axis, and intersecting the axis in $N$, is called the Ordinate of the point $P$.

If the line $P N$ be produced to $P^{\prime}$ so that $N P^{\prime}=N P$, the line $P N P^{\prime}$ is a double ordinate of the curve.

The latus rectum is therefore the double ordinate passing through the focus.

Def. The distance $A N$ of the foot of the ordinate from the vertex is called the Abscissa of the point $P$.

Def. The distance SP is called the focal distance of the point $P$.

It is also described as the radius vector drawn from the focus.
4. Definition of the Tangent to a curve.

If a straight line, drawn through a point $P$ of $a$ curve, meet the curve again in $P^{\prime}$, and if the straight line be turned round the point $P$ until the point $P^{\prime}$ approaches indefinitely near to $P$, the ultimate position of the straight line is the tangent to the curve at $P$.

Thus, if the straight line $A P P^{\prime}$ turn round $P$ until the points $P$ and $P^{\prime}$ coincide, the line in its ultimate position $P T$ is the tangent at $P$.

Def. The normal at any point of a curve is the straight line drawn through the point at right angles to the tangent at that point.

Thus, in the figure, $P G$ is the normal at $P$.
5. We have now given a general method of constructing a conic section, and we have explained the nomenclature which is usually employed. We proceed to demonstrate a few of the properties which are common to all the conic sections.

For the future the word conic will be employed as an abbreviation for conic section.

Prop. II. If the straight line joining two points $P, P^{\prime}$ of a conic meet the directrix in $F$, the straight line $F S$ will bisect the angle between $P S$ and $P^{\prime} S$ produced.

Draw the perpendiculars $P K, P^{\prime} K^{\prime}$, on the directrix.
Then $\quad S P: S P^{\prime}:: P K: P^{\prime} K^{\prime}$, (Fig. Art. 9)

$$
:: P F: P^{\prime} F
$$

Therefore $F S$ bisects the outer angle, at $S$, of the triangle $P S P^{\prime}$. (Euclid, vi. A.)

Cor. If $S Q$ bisect the angle $P S P^{\prime}$, it follows that $F S Q$ is a right angle.
6. Prop. III. The straight line, drawn from the focus to the point in which the tangent meets the directrix, is at right angles to the straight line drawn from the focus to the point of contact.

In the figure of Art. 5, let the point $P^{\prime}$ move along the curve towards $P$; then, as $P^{\prime}$ approaches to coincidence with $P$, the straight line $F P P^{\prime}$ approximates to, and ultimately becomes, the tangent $T P$ at $P$. But, when $P^{\prime}$ coincides with $P$, the line $S Q$ coincides with $S P$, and the angle FSP, which is ultimately TSP , becomes a right angle.

Or, in other words, the portion of the tangent intercepted between the point of contact and the directrix, subtends a right angle at the focus.
7. If a chord $E A P$ be drawn through the vertex, and the point $P$ be ncar the vertex, the angle $P S A$ is small, and $L S N$ which is half the angle $P S N$ is nearly a right angle. The angle $A S E$ is therefore nearly a right angle, and SEX is a small angle, and $A E S$ is, a fortiori, a small angle, and vanishes when $A S E$ is a right angle.

As $P$ approaches to coincidence with $A$, the angle $L S N$ becomes ultimately a right angle, and therefore $A S E$ is ultimately a right angle.

Hence the angle EAX which is the sum or the angles $A E S$, $A S E$, is a right angle when $P$
 coincides with $A$.

But, when $P$ approaches to coincidence with $A$, then EAP approximates to the position of, and ultimately becomes, the tangent at $A$.

The tangent at the vertex is therefore at right angles to the axis.
8. Prop. IV. No straight line can meet a conic in more than two points.

Let $P$ be a point in the curve, draw any straight line $F P$, join $S F$, and draw $S Q$ at right angles to $S F$. Draw $S P^{\prime}$ making the angle $Q S P^{\prime}$ equal to $Q S P$; then $P^{\prime}$ is a point in the curve. For, since $S F$ bisects the outer angle at $S$,

$$
\begin{aligned}
S P^{\prime}: S P & :: P^{\prime} F: P F \\
& :: P^{\prime} K^{\prime}: P K \\
\therefore S P^{\prime}: P^{\prime} K^{\prime} & : S P: P K,
\end{aligned}
$$

and $P^{\prime}$ is a point in the curve.
Also, there is no other point of the curve in the straight line $\boldsymbol{F P}$.

For suppose if possible $P^{\prime \prime}$ to be another point and draw $P^{\prime} K^{\prime \prime}$ perpendicular to the directrix, then

$$
\begin{aligned}
S P^{\prime \prime}: S P & :: P^{\prime} K^{\prime \prime}: P K \\
& :: P^{\prime \prime} F: P F ;
\end{aligned}
$$

therefore $F S$ bisects the angle between $P S$ and $P^{\prime \prime} S$ produced.

But $F S$ bisects the angle between $P S$ and $P^{\prime} S$ produced, which is impossible unless $P^{\prime \prime}$ coincides with $P^{\prime}$.
9. Prop. V. The tangents at the end of a focal chord intersect in the directrix.

For the line $S F$, perpendicular to $S P$, meets the directrix in the same point as the tangent at $P$; and, since $F S$ is also at right angles to $S P^{\prime}$, the tangent at $P^{\prime}$ meets the directrix in the same point $F$. Conversely, if from any point $F$ in the directrix tangents be drawn, the chord of contact, that is, the straight line joining the points of contact, will pass through the focus and will be at right angles to $S F$.

Cor. Hence it follows that the tangents at the ends of the latus rectum pass through the foot of the directrix.
10. Prop. VI. The straight lines joining the extremities of two focal chords intersect in the directrix.

If $P S P, P^{\prime} S p^{\prime}$ be the two chords, the point in which $P P^{\prime}$ meets the directrix is obtained by bisecting the angle $P S P^{\prime}$ and drawing $S F$ at right angles to the bisecting line $S Q$. But this line also bisects the angle $p S p^{\prime}$; therefore $p p^{\prime}$ also passes through $\boldsymbol{F}$.

The line $S F$ bisects the angle $P S p^{\prime}$, and similarly, if $Q S$ produced, bisecting the angle $p S p^{\prime}$, meet the directrix in $F^{\prime}$, the two lines $P p^{\prime}, P^{\prime} p$ will meet in $F^{\prime}$.

It is obvious that the angle $F S F^{\prime}$ is a right angle.
Cor. If the straight line bisecting $P S P^{\prime}$ meet the curre in $q$ and $q^{\prime}$ and $F q, F q^{\prime}$ be joined, these lines will be the tangents at $q$ and $q^{\prime}$. (Prop. $\left.\nabla.\right)$

Hence, if from a point $F$ in the directrix tangents be drawn, and also any straight line $F P P^{\prime}$ cutting the curve in $P$ and $P^{\prime}$, the chord of contact will bisect the angle $\boldsymbol{P S P} \boldsymbol{P}^{\prime}$.
11. Prop. VII. If the tangent at any point $P$ of a conic intersect the directrix in $F$, and the latus rectum produced in $D$,

$$
S D: S F:: S A: A X
$$

Join $S K$; then, observing that $F S P$ and $F K P$ are right angles, a circle can be described about $F S P K$, and
therefore the angles $S F D$, $S K P$ are equal.

Also the angle FSD

$$
\begin{aligned}
& =\text { complement of } D S P \\
& =S P K ;
\end{aligned}
$$

$\therefore$ the triangles $F S D, S P K X$ are similar, and

$$
\begin{aligned}
S D: S F & :: S P: P K \\
& :: S A: A X .
\end{aligned}
$$

Cor. (1). If the tangent at the other end $P^{\prime}$ of the focal chord meet the latus rectum in $D^{\prime}$,

$$
\begin{gathered}
S D^{\prime}: S F:: S A: A X ; \\
\therefore S D=S D^{\prime} .
\end{gathered}
$$

Cor. (2). If $D E$ be the perpendicular from $D$ upon $S P$, the triangles $S D E, S F X$ are similar, and

$$
\begin{aligned}
S E: S X & :: S D: S F \\
& :: S A: A X \\
& :: S R: S X ;
\end{aligned}
$$

$\therefore S E$ is equal to $S R$, the semi-latus rectum.
12. Prop. VIII. The tangents drawn from any point to a conic subtend equal angles at the focus.

Let the tangents $F T P, F^{\prime} T P^{\prime}$ at $P$ and $P^{\prime}$ meet the directrix in $F$ and $F^{\prime}$ and the latus rectum in $D$ and $D^{\prime}$.

Join $S T$ and produce it to meet the directrix in $K$; then

$$
\begin{array}{ll}
\text { n } & K F: S D:: K T: S T \\
& \\
& :: K F^{\prime}: S D^{\prime} \\
\text { Hence } & K F: K F^{\prime}:: S D: S D^{\prime} \\
& \\
& : S F: S F^{\prime} \text { by Prop. vi. }
\end{array}
$$

$\therefore$ the angles TSF, TSF ${ }^{v}$ are equal.

But the angles $F S P^{\prime}, F^{\prime} S P$ are equal, for each is the complement of $F S F^{\prime}$;
$\therefore$ the angles TSP, TSP' are equal.
Cor. Hence it follows that if perpendiculars $T M$, $T M^{\prime}$ be let fall upon $S P$ and $S P^{\prime}$, they are equal in length.

For the two triangles TSM, TSM ${ }^{\prime}$ have the angles $T M S$, TSM respectively equal to the angles TM'S, $T S M^{\prime}$, and the side $T S$ common; and therefore the other sides are equal, and

$$
T M=T M^{\prime} .
$$

13. Prop. IX. If from any point $T$ in the tangent at a point $P$ of a conic, TM be drawn perpendicular to the focal distance $S P$, and TN perpendicular to the directrix,

$$
S M: T N:: S A: A X
$$

For, if $P K$ be perpendicular to the directrix and $S F$ be joined,

$$
\begin{aligned}
S M: S P & :: T F: F P \\
& :: T N: P K ; \\
\therefore S M: T N & :: S P: P K \\
& :: S A: A X .
\end{aligned}
$$

This theorem, which is due to Professor Adams, may be employed to prove Prop. viII.

For if, in the figure of Art. (12), $T M, T M^{\prime}$ be the perpendiculars from $T$ on $S P$ and $S P^{\prime}$, and if $T N$ be the perpendicular on the directrix, $S M$ and $S M^{\prime}$ have each the same ratio to $T N$, and are therefore equal to one another.

Hence the triangles TSM, TSM' are equal in all respects, and the angle $P S P^{\prime}$ is bisected by $S T$.
14. Prop. X. To draw tangents from any point to a conic.

Let $T$ be the point, and let a circle be described about $S$ as centre, the radius of which bears to $T N$ the ratio of $S A: A X$; then, if tangents $T M, T M^{\prime}$ be drawn to the circle the straight lines $S M, S M^{\prime}$, produced if necessary, will intersect the conic in the points of contact of the tangents from $T$.
15. Prop. XI. If $P G$ the normal at $P$ meet the axis of the conic in $G$,

$$
S G: S P:: S A: A X
$$

Let the tangent at $P$ meet the directrix in $F$, and the latus rectum produced in $D$.

Then the angle $S P G=$ the complement of $S P F=P F S$, and the angle $P S G=$ the complement of $F S X=F S D$;
$\therefore$ the triangles $S D F, S P G$ are similar, and
$S G: S P$ :: $S D: S F:: S A: A X$, by Prop. vir.
16. Prop. XII. If a tangent be drawn parallel to $a$ chord of a conic, the portion of this tangent which is intercepted by the tangents at the ends of the chord is bisected at the point of contact.

Let $P P^{\prime}$ be the chord, $T P, T P^{\prime}$ the tangents, and $E Q E^{\prime}$ the tangent parallel to $P P^{\prime}$.

From the focus $S$ draw $S P, S P^{\prime}$ and $S Q$, and draw $T M$, $T M^{\prime}$ perpendicular respectively to $S P, S P^{\prime}$.

Also draw from $E$ perpendiculars $E N, E L$, upon $S P$, $S Q$, and from $E^{\prime}$ perpendiculars $E^{\prime} N^{\prime}, E^{\prime} L^{\prime}$ upon $S P^{\prime}$ and $S Q$.

Then, since $E E^{\prime}$ is parallel to $P P^{\prime}$
$T P: E P:: T P^{\prime}: E^{\prime} P^{\prime}$,
but
$T P: E P:: T M: E N$,

$$
\begin{aligned}
& T P^{\prime}: E^{\prime} P^{\prime}:: T M^{\prime}: E^{\prime} N^{\prime} ; \\
& \therefore T M: E N:: T M^{\prime}: E N^{\prime} ;
\end{aligned}
$$

but $T M=T M^{\prime}$, Cor. Prop. vili ;

$$
\therefore E N=E^{\prime} N^{\prime} .
$$

Again, by the same corollary,

$$
\begin{gathered}
E N=E L \text { and } E^{\prime} N^{\prime}=E^{\prime} L^{\prime} ; \\
\therefore E L=E^{\prime} L^{\prime},
\end{gathered}
$$

and, the triangles $E L Q, E^{\prime} L^{\prime} Q$ being similar,

$$
E Q=E Q .
$$

Cor. If $T Q$ be produced to meet $P P^{\prime}$ in $V$,

$$
P V: E Q:: T V: T Q,
$$

and

$$
P^{\prime} V: E^{\prime} Q:: T V: T Q ;
$$

$$
\therefore P V=P^{\prime} V,
$$

that is, $P P^{\prime}$ is bisected in $V$.
Hence, if tangents be drawn at the ends of any chord of a conic, the point of intersection of these tangents, the middle point of the chord, and the point of contact of the tangent parallel to the chord, all lie in one straight line.
17. Prop. XIII. The semi-latus rectum is the harmonic mean between the two segments of any focal chord of a conic.

Let $P S P^{\prime}$ be a focal chord, and draw the ordinates $P N, P^{\prime} N^{\prime}$.

Then the triangles $S P N, S P^{\prime} N^{\prime}$ are similar;

$$
\begin{aligned}
\therefore S P: S P^{\prime} & :: S N: S N^{\prime} \\
& :: N X-S X: S X-N^{\prime} X \\
& :: S P-S R: S R-S P^{\prime},
\end{aligned}
$$

since $S P, S R, S P^{\prime}$ are proportional to $N X, S X$, and $N^{\prime} X$.

Cor. Since $S P: S P-S R=S P . S P^{\prime}: S P . S P^{\prime}-S R . S P ;$ and $S P^{\prime}: S R-S P^{\prime}=S P . S P^{\prime}: S R . S P-S P . S P^{\prime}$, it follows that $S R . P P^{\prime}=2 S P . S P^{\prime}$.

Hence, if $P S P^{\prime}, Q S Q^{\prime}$ are two focal chords, it follows that $P P^{\prime}: Q Q^{\prime}:: S P . S P^{\prime}: S Q . S Q^{\prime}$.
18. Prop. XIV. If from $G$, the point in which the normal at $P$ meets the axis, GL be drawn perpendicular to $S P$, the length $P L$ is equal to the semi-latus rectum.

Let the tangent at $P$ meet the directrix in $F$, and join SF.

Then $P L G, P S F$ are similar triangles ;

$$
\therefore P L: L G:: S F: S P .
$$

Also $S L G$ and $S F X$ are similar triangles ;

$$
\therefore L G: S X:: S G: S F .
$$

Hence

$$
\begin{aligned}
P L: S X & :: S G: S P \\
& :: S A: A X, \text { Art. (15), } \\
S R: S X & :: S A: A X, \text { Art. (2); } \\
\therefore P L & =S R .
\end{aligned}
$$

19. Prop. XV. A focal chord is divided harmonically at the focus and the point where it meets the directrix.

Let $P S P^{\prime}$ produced meet the directrix in $F$, and draw $P K, P^{\prime} K^{\prime}$ perpendicular to the directrix, fig. Art. 17.
B. c. s.

$$
\text { Then } \begin{aligned}
P F: P^{\prime} F & :: P K: P^{\prime} K^{\prime} \\
& :: S P: S P^{\prime} \\
& :: P F-S F: S F-P^{\prime} F ;
\end{aligned}
$$

that is, $P F, S F$, and $P^{\prime} F$ are in harmonic progression, and the line $P P^{\prime}$ is divided harmonically at $S$ and $F$.
20. Prop. XVI. If from any point $F$ in the directrix tangents be drawn, and also any straight line $F P P^{\prime}$ cutting the curve in $P$ and $P^{\prime}$, the chord $P P^{\prime}$ is divided harmonically at $F$ and its point of intersection with the chord of contact.

For, if $Q S Q^{\prime}$ be the chord of contact, it bisects the angle $P S P^{\prime}$, (cor. Prop. VI.), and $\therefore$, if $V$ be the point of intersection of $S Q$ and $P P^{\prime}$,

$$
\begin{aligned}
F P^{\prime}: F P & :: S P^{\prime}: S P \\
& :: P^{\prime} V: P V \\
& : F P^{\prime}-F V: F V-F P .
\end{aligned}
$$

Hence $F V$ is an harmonic mean between $F P$ and $F P$.
The last two theorems are particular cases of more general theorems, which will appear hereafter.

## EXAMPLES.

1. Having given a point $P$ of a conic, the tangent at $P$, and the directrix, find the locus of the focus.
2. If $P S Q$ be a focal chord, and $X$ the foot of the directrix, $X P$ and $X Q$ are equally inclined to the axis.
3. If a chord $P Q$ meet the directrix in $F, S P$ and $S Q$ are equally inclined to $S F$.
4. If $P K$ be the perpendicular from a point $P$ of a conic on the directrix, and $S K$ meet the tangent at the vertex in $E$, the angles $S P E, K P E$ are equal.
5. If the tangent at $P$ meet the directrix in $F$ and the axis in $T$, the angles $K S F, F T S$ are equal.
6. $P S P^{\prime}$ is a focal chord, $P N, P^{\prime} N^{\prime}$ are the ordinates, and $P K, P^{\prime} K^{\prime}$ perpendiculars on the directrix ; if $K N, K^{\prime} N^{\prime}$ meet in $L$, the triangle $L N N^{\prime}$ is isosceles.
7. The focal distance of a point on a conic is equal to the length of the ordinate produced to meet the tangent at the end of the latus rectum.
8. The normal at any point bears to the semi-latus rectum the ratio of the focal distance of the point to the distance of the focus from the tangent.
9. Given the focus and directrix, and a tangent, find the point of contact.
10. The chord of a conic is given in length; prove that, if this length exceed the latus rectum, the distance from the directrix of the middle point of the chord is least when the chord passes through the focus.
11. The portion of any tangent to a conic, intercepted between two fixed tangents, subtends a constant angle at the focus.
12. Given two points of a conic, and the directrix, find the locus of the focus.
13. From any fixed point in the axis a line is drawn perpendicular to the tangent at $P$ and meeting $S P$ in $R$; the locus of $R$ is a circle.
14. If the tangent at the end of the latus rectum meet the tangent at the vertex in $T, A T=A S$.
15. $T P, T Q$ are the tangents at the points $P, Q$ of a conic and $P Q$ meets the directrix in $R$; prove that $R S T$ is a right angle.

2-2
16. $S R$ being the semi-latus rectum, if $R A$ meet the direotrix in $E$, and $S E$ meet the tangent at the vertex in $T$,

$$
A T=A S
$$

17. If from any point $T$, in the tangent at $P, T M$ be drawn perpendicular to $S P$, and $T N$ perpendicular to the transverse axis, meeting the curve in $R, S M=S R$.
18. If the chords $P Q, P^{\prime} Q$ meet the directrix in $F$ and $F^{\prime}$, the angle $F S F^{\prime \prime}$ is half $P S P^{\prime}$.
19. If $P N$ be the ordinate, $P G$ the normal, and $G L$ the perpendicular from $G$ upon $S P$,

$$
G L: P N:: S A: A X
$$

20. If normals be drawn at the ends of a focal chord, a line through their intersection parallel to the axis will bisect the chord.
21. If $P S p$ be a focal chord of a conic, $Q$ any point of the conic, and if $P Q, p Q$ meet the directrix in $D$ and $E, D S E$ is a right angle.
[This theorem includes, as particular cases, theorems subsequently given in Articles 25, 27, 53, and 90.]
22. If $P S P^{\prime}$ be a focal chord, and $R R^{\prime}$ the latus rectum,

$$
4 S P . S P^{\prime}=R R^{\prime} . P P^{\prime}
$$

23. If $E$ be the foot of the perpendicular let fall upon $P S P^{\prime}$ from the point of intersection of the normals at $P$ and $P^{\prime}$,

$$
P E=S P^{\prime} \text { and } P^{\prime} E=S P .
$$

24. If a circle be described on the latus rectum as diameter, and if the common tangent to the conic and circle touch the conic in $P$ and the circle in $Q$, the angle $P S Q$ is bisected by the latus rectum. (Refer to Cor. 2. Art. 11.)
25. Given two points, the focus, and the eccentricity, determine the position of the axis.
26. If a chord $P Q$ subtend a constant angle at the focus, the locus of the intersection of the tangents at $P$ and $Q$ is a conic with the same focus and directrix.
27. $P p$ is any chord of a conic, $P G, p g$ the normals, $G, g$ being on the axis; $G L, g l$ are perpendiculars on $P p$; shew that $P L$ and $p l$ are equal to one another.

## CHAPTER II.

## THE PARABOLA.

Def. A parabola is the curve traced out by a point which moves in such a manner that its distance from a given point is always equal to its distance from a given straight line.

Tracing the Curve.

21. Let $S$ be the focus, $E X$ the directrix, and $S X$ the perpendicular on $E X$. Then, bisecting $S X$ in $A$, the point $A$ is the vertex; and, if from any point $E$ in the directrix, $E A P, E S L$ be drawn, and from $S$ the straight line $S P$ meeting $E A$ produced in $P$, and making the angle $P S L$ equal to $L S S N$, we obtain \{as in Art. (1) \}, a point $P$ in the curve.

For

$$
\begin{aligned}
P L: & P K:: S A: A X, \\
& \therefore P L=P K .
\end{aligned}
$$

and

But

$$
S P=P L, \text { and } \therefore S P=P K
$$

Again, drawing $E P^{\prime}$ parallel to the axis and meeting in $P^{\prime}$ the line $P S$ produced, we obtain the other extremity of the focal chord $P S P^{\prime}$.

For the angle $\quad E S P^{\prime}=P S L=P L S$

$$
=S E P^{\prime},
$$

and

$$
\therefore S P^{\prime}=P^{\prime} E \text {, }
$$

and $P^{\prime}$ is a point in the parabola.
The curve lies wholly on the same side of the directrix;

for, if $P^{\prime}$ be a point on the other side, and $S N$ be perpendicular to $P^{\prime} K, S P^{\prime}$ is greater than $P^{\prime} N$, and therefore is greater than $P^{\prime} K$.

Again, a straight line parallel to the axis meets the curve in one point only.

For, if possible, let $P^{\prime \prime}$ be another point of the curve in $K P$ produced.

Then

$$
\begin{gathered}
S P=P K \text { and } S P^{\prime \prime}=P^{\prime \prime} K ; \\
\therefore P P^{\prime \prime}=S P^{\prime \prime}-S P,
\end{gathered}
$$

or

$$
P P^{\prime \prime}+S P=S P^{\prime \prime}
$$

which is impossible.
Lastly, the curve has infinite branches; for, since $P S=P K=P L$, it follows that $P$ is the centre of the circle passing through $K, S$, and $L$, and therefore the angle $K S L$ in a semicircle is a right angle; hence it follows that, as $E$ approaches $X$, the point $K$ moves away from $\boldsymbol{X}$, and therefore the point $P$ moves away from the axis, its distance becoming larger as the distance $E X$ diminishes. Since $E S K$ is a right angle the rectangle $E X . K X$ is equal to $S X^{2}$, and therefore when $E X$ is indefinitely small, $K X$ is indefinitely large. The curve therefore bas two branches proceeding to infinity.
22. Prop. I. The distance from the focus of a point inside a parabola is less, and of a point outside is greater than its distance from the directrix.

If $Q$ be the point inside, let fall the perpendicular QPK on the directrix, meeting the curve in $P$.
Then $S P+P Q>N Q$, but $S P+P Q$

$$
=P K+P Q=Q K,
$$

$$
\therefore S Q<Q K .
$$

If $Q^{\prime}$ be outside, and
 between $P$ and $K$,

$$
\begin{gathered}
S Q^{\prime}+P Q^{\prime}>S P, \\
\therefore S Q^{\prime}>Q^{\prime} K .
\end{gathered}
$$

If $Q^{\prime}$ lie in $P K$ produced,

$$
\begin{aligned}
& S Q^{\prime}+S P>P Q^{\prime}, \\
& \therefore S Q^{\prime}>K Q^{\prime} .
\end{aligned}
$$

and
23. Prop. II. The Latus Rectum $=4$. AS .

For if, Fig. Art. 22, $L S L^{\prime}$ be the Latus Rectum, drawing $L K^{\prime}$ at right angles to the directrix, we have

$$
\begin{gathered}
L S=L K^{\prime}=S X=2 A S \\
\therefore L S L^{\prime}=4 . A S .
\end{gathered}
$$

24. Mechanical construction of the Parabola.

Take a rigid bar $E K L$, of which the portions $E K, K L$ are at right angles to each other, and fasten a string to the end $L$, the length of which is $L K$. Then if the other end of the
 string be fastened to $S$, and the bar be made to slide along the directrix, a pencil at $P$, keeping the string stretched against the bar, will trace out a portion of a parabola.
25. Prop. III. If $P N$ be the ordinate of a point $P$, $P N^{2}=4 A S . A N$.
Draw the lines PAE, ESL, KPL, and join SK.
Then $S P=P L=P K$. Hence $K S L$, and $\therefore K S E$, is a right angle, and $E X . K X=S X^{2}$
also

$$
A N: A X:: P N: E X
$$

or

$$
=4 A S^{2} ;
$$

$$
A N: A S:: P N^{2}: E X . K X
$$

$$
4 A S . A N: 4 A S^{2}:: P N^{2}: 4 A S^{2}
$$

$$
\therefore P N^{2}=4 A S . A N .
$$

26. Conversely, if it be known that at every point of a curve the relation $P N^{2}=4 A S$. $A N$ holds true, the curve is a parabola.

In $N A$ produced take $A X$ equal to $A S$, draw $E X K$ at right angles to $X N$, and $K P L$ parallel to $X N$; also draw $P A E$, and $E S L$.

Then

$$
\begin{gathered}
A N: A X:: P N: E X, \\
A N: A S:: P N^{2}: E X . K X, \\
P N^{2}=4 A S . A N ; \\
\therefore E X . K X=4 A S^{2}=S X^{2} .
\end{gathered}
$$

but

Hence $K S E$, and $\therefore K S L$, is a right angle,
and, since

$$
S A=A X, P L=P K,
$$

and therefore $P$ is the centre of the circle passing through $K, S$, and $L$.

Heuce it follows that $S P=P K$, which is the definition of a parabola.
27. Prop. IV. If from the ends of a focal chord perpendiculars be let fall upon the directrix, the intercepted portion of the directrix subtends a right angle at the focus.

For, if the straight line through $E$ parallel to the axis meet $P S$ in $P^{\prime}, P^{\prime}$ is the other extremity of the focal chord $P S$, and, as in Art. 25, $K S E$ is a right angle.

Cor. Since $E S$ bisects the angle $A S P^{\prime}$, Art. 21, it follows that $K S$ bisects the angle $A S P$.
28. Prop. V. The tangent at any point $P$ bisects the angle between the focal distance SP and the perpendicular $\boldsymbol{P K}$ on the directrix.

Let $\boldsymbol{F}$ be the point in which the tangent meets the directrix, and join $S F$.

We have shewn, (Art. 6) that $F S P$ is a right angle, and, since $S P=P K$, and $P F$ is common to the right-angled triangles $S P F, K P F$, it follows that these triangles are equal in all respects, and therefore the angle

$$
S P F=F P K .
$$

In other words, the tangent at any point is equally inclined to the focal distance and the axis.

Cor. It has been shewn, in Art. (9), that the tangents at the ends of a focal chord intersect in the directrix, and therefore, if $P S$ produced meet the curve in $P^{\prime}, F P^{\prime}$ is the tangent at $P^{\prime}$, and bisects the angle between $S P^{\prime}$ and the perpendicular from $P^{\prime}$ on the directrix.
29. Prop. VI. The tangents at the ends of a focal chord intersect at right angles in the directrix.

Let $P S P^{\prime}$ be the chord, and $P F, P^{\prime} F$ the tangents meeting the directrix in $F$.

Let fall the perpendiculars $P K$, $P K^{\prime}$, and join $S K, S K^{\prime}$.

The angle $P^{\prime} S K^{\prime}=\frac{1}{2} P^{\prime} S X$

$$
=\frac{1}{2} S P K=S P F,
$$

$\therefore S K^{\prime}$ is parallel to $P F$, and, similarly, $S K$ is parallel to $P^{\prime} F$.

But (Art. 27) $K S K^{\prime}$ is a right angle;
$\therefore P P^{\prime}$ is a right angle.
30. Prop. VII. If the tangent at any point $P$ of a parabola meet the axis in $T$, and $P N$ be the ordinate of $P$, then

$$
A T=A N
$$

Draw $P K$ perpendicular to the directrix.

The angle $S P T$

$$
\begin{aligned}
& =T P K \\
& =P T S
\end{aligned}
$$

$\therefore S T=S P$
$=P K$

$$
=N X
$$

But

$$
S T=S A+A T
$$

and

$$
N X=A N+A X
$$

$$
\therefore \text { since } S A=A X
$$

$$
A T=A N
$$

Def. The line $N T$ is called the sub-tangent.
The sub-tangent is therefore twice the abscissa of the point of contact.
31. Prop. VIII. The foot of the perpendicular from the focus on the tangent at any point $P$ of a parabola lies on the tangent at the vertex, and the perpendicular is a mean proportional between SP and SA.

Taking the figure of the previous article, join $S K$ meeting $P T$ in $Y$.

Then $S P=P K$, and $P Y$ is common to the two triangles $S P Y, K P Y$;
also the angle $S P Y=Y P K$;
$\therefore$ the angle $S Y P=P Y K$,
and $S Y$ is perpendicular to $P T$.
Also $S Y=K Y$, and $S A=A X, \therefore S Y: Y K:: S A: A X$, and $A Y$ is parallel to $K X$.

Hence, $A Y$ is at right angles to $A S$, and is therefore the tangent at the vertex.

Again, the angle $S P Y=S T Y=S Y A$, and the triangles $S P Y, S Y A$ are therefore similar;

$$
\begin{array}{rl}
\therefore S P & S Y:: S Y: S A \\
& \text { or } S Y^{2}=S P . S A
\end{array}
$$

32. Prop. IX. In the parabola the subnormal is constant and equal to the semi-latus Rectum.

Def. The distance between the foot of the ordinate of $P$ and the point in which the normal at $P$ meets the axis is called the subnormal.

In the figure $P G$ is the normal and $P T$ the tangent.
It has been shewn that the angle $S P K$ is bisected by $P T$, and hence it follows that $S P L$ is bisected by $P G$, and that the angle $S P G=G P L=P G S$;
hence

$$
\begin{aligned}
S G & =S P=S T \\
& =S A+A T=S A+A N \\
& =2 A S+S N ;
\end{aligned}
$$

$\therefore$ the subnormal $N G=2 A S$.
33. Cor. If $G l$ be drawn perpendicular to $S P$, the angle $G P l=$ the complement of $S P T$,

$$
\begin{aligned}
& =\text { the complement of } S T P, \\
& =P G N,
\end{aligned}
$$

and the two right-angled triangles $G P N, G P l$ have their angles equal and the side $G P$ common; hence the triangles are equal, and

$$
\begin{aligned}
P l & =N G=2 A S \\
& =\text { the semi-latus Rectum. }
\end{aligned}
$$

It has been already shewn, Art. (18), that this property is a general property of all conics.
34. Prop. X. To draw tangents to a parabola from an external point.

For this purpose we may employ the general construction given in Art. (14), or, for the special case of the paraboia, the following construction.

Let $Q$ be the external point, join $S Q$, and upon $S Q$ as diameter describe a circle intersecting the tangent at the vertex in $Y$ and $Y^{\prime}$. Join $Y Q, Y^{\prime} Q$; these are tangents to the parabola.

Draw $S P$, so as to make the angle $Y S P$ equal to $Y S A$, and to meet $Y Q$ in $P$, and let fall the perpendicular $P N$ upon the axis.

Then, $S Y Q$ is a right angle, since it is the angle in a semicircle, and, $T$ being the point in which $Q Y$ produced meets the axis, the two triangles $S Y P, S Y T$ are equal in all respects;

$$
\therefore S P=S T, \text { and } Y T=Y P
$$

But $A Y$ is parallel to $P N$;

$$
\therefore A T=A N
$$

Hence

$$
\begin{aligned}
S P & =S T=S A+A T \\
& =A X+A N \\
& =N X,
\end{aligned}
$$

and $P$ is a point in the parabola.
Moreover, if $P K$ be perpendicular to the directrix, the angle $S P Y=S T P=Y P K$, and $P Y$ is the tangent at $P$. Art. (28).

Similarly, by making the angle $Y^{\prime} S P^{\prime}$ equal to $A S Y^{\prime}$, we obtain the point of contact of the other tangent $Q Y^{\prime}$.
35. Prop. XI. If from a point $Q$ tangents $Q P, Q P^{\prime}$ be drawn to a parabola, the two triangles $S \quad Q, S Q P^{\prime}$ are similar, and $S Q$ is a mean proportional between $S P$ and $S P$.

Produce $P Q$ to meet the axis in $T$, and draw $S Y, S Y^{\prime}$ perpendicularly on the tangents. Then $Y$ and $Y^{\prime}$ are points in the tangent at $A$.

The angle

$$
\begin{aligned}
S P Q & =S T Y \\
& =S Y A \\
& =S Q P^{\prime},
\end{aligned}
$$

since $S, Y^{\prime}, Y, Q$ are points on a circle, and $S Y A, S Q P^{\prime}$ are in the same segment.

Also, by the theorem of Art. (12), the angle

$$
P S Q=Q S P^{\prime} ;
$$

therefore the triangles $P S Q, Q S P^{\prime}$ are similar, and

$$
S P: S Q:: S Q: S P^{\prime} .
$$

36. From the theorem of Art. 35 the following, which is often useful, immediately follows.

If from any points in a given tangent of a parabola, tangents be drawn to the curve, the angles which these tangents make with the focal distances of the points from which they are drawn are all equal.

For each of them, by the theorem, is equal to the angle between the given tangent and the focal distance of the point of contact.
37. Since the two triangles $P S Q, Q S P^{\prime}$ are similar, we have

$$
\begin{aligned}
P Q: P^{\prime} Q:: S P: S Q \\
P Q: P^{\prime} Q:: S Q: S P^{\prime}, \\
\therefore P Q^{2}: P^{\prime} Q^{2}:: S P: S P^{\prime} ;
\end{aligned}
$$

and
that is, the squares of the tangents from any point are proportional to the focal distances of the points of contact.

This will be found to be a particular case of a subsequent Theorem.
38. Prop. XII. The external angle between two tangents is half the angle subtended at the focus by the chord of contact.

Let the tangents at $P$ and $P^{\prime}$ intersect each other in $Q$ and the axis $A S N$ in $T$ and $T^{\prime}$.

Join $S P, S P^{\prime}$; then the angles $S P T, S T P$ are equal, and $\therefore S T P$ is half the angle $P S N$; similarly $S T^{\prime \prime} P^{\prime}$ is half $P^{\prime} S N$.

But $T Q T^{v}$ is equal to the difference between $S T P$ and $S T^{\prime \prime} P^{\prime}$, and is therefore equal to half the difference between $P S N$ and $P^{\prime} S N$, that is to half the angle $P S P^{\prime}$.

Hence, joining $S Q, T Q T^{v}$ is equal to each of the angles $P S Q, P^{\prime} S Q$.
39. Prop. XIII. The tangents drawn to a parabola from any point make the same angles, respectively, with the axis and the focal distance of the point.

Let $Q P, Q P^{\prime}$ be the tangents ; join $S P$, and draw $Q E$ parallel to the axis, and meeting $S P$ in $E$.

Then, if $P Q$ meet the axis in $T$, the angle

$$
\begin{aligned}
E Q P & =S T P=S P Q \\
& =S Q P^{\prime} . \quad \text { Art. (36). }
\end{aligned}
$$

i. e. $Q P$ and $Q P^{\prime}$ respectively make the same angles with the axis and with $Q S$.
40. Conceive a parabola to be drawn passing through $Q$, having $S$ for its focus, $S N$ for its axis, and its vertex on the same side of $S$ as the vertex $A$ of the given parabola. Then the normal at $Q$ to this new parabola bisects the angle $S Q E$; therefore the angles which $Q P$ and $Q P^{\prime}$ make with the normal at $Q$ are equal.

Hence the theorem,
If from any point in a parabola, tangents be drawn to a confocal and co-axial parabola, the normal at the point will bisect the angle between the tangents.

In this enunciation the words co-axial and confocal are intended to imply, not merely the coincidence of the axes, but also that the vertices of the two parabolas are on the same side of their common focus.

The reason for this will appear when we shall have discussed the analogous property of the ellipse.
41. Prop. XIV. The circle passing through the points of intersection of three tangents passes also through the focus.

Let $Q, P, Q^{\prime}$ be the three points of contact, and $F, T, F^{\prime}$ the intersections of the tangents.

In Art. (35) it has been shewn that, if $F P, F Q$ be tangents, the angle

$$
S Q F=S F P .
$$

Similarly $T Q, T Q^{\prime}$ being tangents, the angle

$$
S Q T=S T Q^{\prime},
$$

hence the angle $S F F^{\prime \prime}$ or $S F P=S Q T$,

$$
=S T F^{\prime \prime},
$$

and a circle can be drawn through $S, F, T$, and $F^{\prime}$.
42. Def. A straight line drawn parallel to the axis through any point of a parabola is called a diameter.

Prop. XV. If from any point T tangents TQ, TQ' be drawn to a parabola, the point $T$ is equidistant from the diameters passing through $Q$ and $Q$, and the diameter drawn through the point $T$ bisects the chord of contact.

Join $S Q, S Q^{\prime}$, and draw $T M, T M^{\prime}$ perpendicular respectively to $S Q$ and $S Q$.

Also draw $N T N^{\prime}$ perpendicular to the diameters through $Q$ and $Q^{\prime}$, and meeting those diameters in $N$ and $N^{\prime}$.

Then, since TS bisects the angle $Q S Q^{\prime}$,

$$
T M=T M^{\prime} ;
$$

and, since $T Q$ bisects the angle $S Q N$,

$$
T N=T M .
$$

Similarly

$$
T N^{\prime}=T M^{\prime},
$$

$$
\therefore T N=T N^{\prime}
$$

Again, join $Q Q^{\prime}$, and draw the diameter $T V$ meeting $Q Q^{\prime}$ in $V$; also let $Q T$ produced meet $Q^{\prime} N^{\prime}$ in $R$; then

$$
\begin{aligned}
Q V: V Q^{\prime} & :: Q T: T R \\
& :: T N: T N^{\prime},
\end{aligned}
$$

since the triangles $Q T N, R T N^{\prime}$ are similar ;

$$
\therefore Q V=V Q^{\prime} .
$$

Hence the diameter through the muddle point of a chord passes, when produced, through the point of intersection of the tangents at the ends of the chord.

It should be noticed that any straight line drawn through $T$ and terminated by $Q N$ and $Q^{\prime} N^{\prime}$ is bisected at $T$.
43. Prop. XVI. Any diameter bisects all chords parallel to the tangent at its extremity, and passes through the point of intersection of the tangents at the ends of any of these chords.

Let $Q Q^{\prime}$ be a chord parallel to the tangent at $P$, and through the point of intersection $T$ of the tangents at $Q$ and $Q^{\prime}$ draw $F T F^{\prime}$ parallel to $Q Q^{\prime}$ and terminated at $F$ and $F^{\prime}$ by the diameters through $Q$ and $Q^{\prime}$.

Let the tangent at $P$ meet $T Q, T Q^{\prime}$ in $E$ and $E^{\prime}$, and $Q F, Q^{\prime} F^{\prime}$ in $G$ and $G^{\prime}$.

Then

$$
\begin{aligned}
E G: T F & :: E Q: T Q \\
& :: E Q^{\prime}: T Q^{\prime} \\
& :: E^{\prime} G^{\prime}: T F^{\prime} .
\end{aligned}
$$

But $T F=T F^{\prime}$, since, Art. (42), $T$ is equidistant from $Q G$ and $Q^{\prime} G^{\prime}$,

$$
\therefore E G=E^{\prime} G^{\prime} \text {. }
$$

Also, $E P=E G$, since $E$ is equidistant from $Q G$ and $P V$,

$$
\therefore E P=E^{\prime} P \text { and } G P=P G^{\prime} .
$$

Hence, $P V$ being the diameter at $P$,

$$
Q V=V Q^{\prime} .
$$

Again, since $T, P, V$ are each equidistant from the parallel straight lines $Q F, Q^{\prime} F^{\prime}$, it follows that $T P V$ is a straight line, or that the diameter $V P$ passes through $T$.

We have shewn that $G E, E P, P E^{\prime}, E^{\prime} G^{\prime}$ are all equal, and we hence infer that

$$
E E^{\prime}=\frac{1}{2} G G^{\prime}=\frac{1}{2} Q Q^{\prime},
$$

and consequently that $T P=\frac{1}{2} T V$ or that $T P=P V$.
Hence $i$ appears, that the diameter through the point of intersection of a pair of tangents passes through the point of contact of the tangent parallel to the chord of contact, and also through the middle point of the chord of contact; and that the portion of the diameter between the point of intersection of the tangents and the middle point of the chord of contact is bisected at the point of contact of the parallel tangent.

We may observe that in proving that $E E^{\prime}$ is bisected at $P$, we have demonstrated a theorem already shewn, Art. (16), to be true for all conics.
44. Def. The line $Q V$, parallel to the tangent at $P$, and terminated by the diameter $P V$, is called an ordinate of that diameter, and $Q Q^{\prime}$ is the double ordinate. The point $P$, the end of the diameter, is called its vertex.

We observe that tangents at the ends of any chord intersect in the diameter which bisects the chord, and that the distance of this point from the vertex is equal to the distance of the vertex from the middle point of the chord.

Def. The chord through the focus parallel to the tangent at any point is called the parameter of the diameter passing through the point.

Prop. XVII. The parameter of any diameter is four times the focal distance of the vertex of that diameter.

Let $P$ be the vertex, and $Q S Q^{\prime}$ the parameter, $T$ the point of intersection of the tangents at $Q$ and $Q^{\prime}$, and $F P \cdot F^{\prime \prime}$ the tangent at $P$.

Then, since $F S$ and $F^{\prime \prime} S$ bisect respectively the angles

$P S Q, P S Q^{\prime}, F S F^{\prime}$ is a right angle, and, $P$ being the middle point of $F F^{\prime \prime}, S P=P F=P F^{\prime}$.

Hence $Q Q^{\prime}$, which is double $F F^{\prime}$, is four times $S P$.
45. Prop. XVIII. If $Q V Q^{\prime}$ be a double ordinate of a diameter $P V, Q V$ is a mean proportional between $P V$ and the parameter of $P$.

Let $F P F^{\prime}$ be the tangent at $P$, and draw the parameter through $S$ meeting $P V$ in $U$.

The angle $S U T=F P U=S P F^{\prime \prime}$, Art. 28;
and, since the angles $S F Q, S P F$ are equal (Art. 35), it follows that the angles $S F T, S P F^{y}$ are equal;
$\therefore S U T=S F T$, and $U$ is a point in the circle passing through $S F T F^{\prime \prime}$.

Hence, $Q V$ being twice $P F$,

$$
Q V^{2}=4 P F^{2}=4 P U \cdot P T ;
$$

but

$$
P U=S P
$$

for the angle $S U P=F P U=S P F^{\prime}=P S U$; and

$$
\begin{aligned}
P T & =P V, \\
\therefore Q V^{2} & =4 S P . P V .
\end{aligned}
$$

46. Prop. XIX. If $Q V Q^{\prime}$ be a double ordinate of a diameter $P V$, and $Q D$ the perpendicular from $Q$ upon $P V, Q D$ is a mean proportional between $P V$ and the latus rectum.

Let the tangent at $P$ meet the tangent at the vertex in $Y$, and join $S Y$.

The angle $Q V D=S P Y=S Y A$, and therefore the triangles $Q V D, S A Y$ are similar ;
and $\quad Q D^{2}: Q V^{2}:: A S^{2}: S Y^{2}$
:: $A S^{2}: A S . S P$
:: $A S: S P$
:: 4AS.PV : $4 S P . P V$,
but

$$
Q V^{2}=4 S P \cdot P V
$$

$$
\therefore Q D^{2}=4 A S . P V
$$

47. Prop. XX. If from any point, within or without a parabola, two straight lines be drawn in given directions and intersecting the curve, the ratio of the rectangles of the segments is independent of the position of the point.

From any point $O$ draw a straight line intersecting the parabola in $Q$ and $Q^{\prime}$, and draw the diameter $O E$, meeting the curve in $E$.

If $P V$ be the diameter bisecting $Q Q^{\prime}$, and $E U$ the ordinate, $O Q . O Q^{\prime}=O V^{2}-Q V^{2}$

$$
\begin{aligned}
& =E U^{2}-Q V^{2}=4 S P \cdot P U-4 S P \cdot P V \\
& =4 S P \cdot O E .
\end{aligned}
$$

Similarly, if $O R R^{\prime}$ be any other intersecting line and $P^{\prime}$ the vertex of the diameter bisecting $R R^{\prime}$,

$$
O R . O R^{\prime}=4 S P^{\prime} . O E
$$

$$
\therefore O Q . O Q^{\prime}: O R . O R^{\prime}: S P: S P^{\prime},
$$

that is, the ratio of the rectangles depends only on the positions of $P$ and $P^{\prime}$, and, if the lines $O Q Q^{\prime}, O R R^{\prime}$ are drawn parallel to given straight lines, these points $P, P^{\prime}$ are fixed.

It will be easily seen that the proof is the same if the point $O$ be within the parabola.

If the lines $O Q Q^{\prime}, O R R^{\prime}$ be moved parallel to themselves
until they become the tangents at $P$ and $P^{\prime}$, we shall then obtain, if these tangents intersect in $T$,

$$
T P^{2}: T P^{\prime 2}:: S P: S P^{\prime}
$$

a result previously obtained (Art. 37).
Again if $Q S Q^{\prime}, R S R^{\prime}$ be the focal chords parallel to $T P$ and $T P^{\prime}$, it follows that

$$
T P^{2}: T P^{\prime 2}:: Q S . S Q^{\prime}: R S . S R^{\prime},
$$

$\therefore$, cor. Art. 17, $T P^{2}$ : $T P^{\prime 2}:: Q Q^{\prime}: R R^{\prime}$.
48. Prop. XXI. If from a point $O$, outside a parabola, a tangent OM, and a chord OAB be drawn, and if the diameter ME meet the chord in E,

$$
O E^{2}=O \Lambda . O B .
$$

Let $P$ be the point of contact of the tangent parallel to $O A B$, and let $O M, M E$ meet this tangent in $T$ and $F$.

Draw $T V$ parallel to the axis and meeting $P M$ in $V$;
then

$$
\begin{aligned}
& O A . O B: O M^{2}:: T P^{2}: T M^{2}(\text { Art. 47 }), \\
&:: T F^{2}: T M^{2},
\end{aligned}
$$

since $P M$ is bisected in $V$;
also

$$
\begin{gathered}
T F: T M:: O E: O M ; \\
\therefore O E^{2}=O A . O B .
\end{gathered}
$$

## The Parabola.

Cor. If $A L, B N$ be the ordinates, parallel to $O M$, of $A$, and $B, M L, M E$, and $M N$ are proportional to $O A, O E$ and $O B$, and therefore

$$
M E^{2}=M L . M N .
$$

This theorem may be also stated in the following form:
If a chord AB of a parabola intersect a diameter in the point $E$, the distance of the point $E$ from the tangent at the end of the diameter is a mean proportional between the distances of the points $A$ and $B$ from the same tangent.
49. Prop. XXII. If a circle intersect a parabola in four points, the two straight lines constituting any one of the three pairs of the chords of intersection are equally inclined to the axis.

Let $Q, Q^{\prime}, R, R^{\prime}$ be the four points of intersection;
then $O Q . O Q^{\prime}=O R . O R^{\prime}$, and therefore $S P, S P^{\prime}$ are equal, Art. (47).

But, if $S P, S P^{\prime}$ be equal, the points $P, P^{\prime}$ are on opposite sides of, and are equidistant from the axis, and the tangents at $P$ and $P^{\prime}$ are therefore equally inclined to the axis.

Hence the chords $Q Q^{\prime}, R R^{\prime}$, which are parallel to these tangents, are equally inclined to the axis.

In the same manner it may be shewn that $Q R, Q^{\prime} R^{\prime}$ are equally inclined to the axis, as also $Q R^{\prime}, Q^{\prime} R$.
50. Conversely, if two chords $Q Q^{\prime}, R R^{\prime}$, which are not parallel, make equal angles with the axis, a circle can be drawn through $Q Q^{\prime} R^{\prime} R$.

For, if the chords intersect in $O$, and $O E$ be drawn parallel to the axis and meeting the curve in $E$, it may be shewn as above that

$$
O Q . O Q^{\prime}=4 S P . O E \text { and } O R . O R^{\prime}=4 S P^{\prime} . O E,
$$

$P$ and $P^{\prime}$ being the vertices of the diameters bisecting the chords.

But the tangents at $P$ and $P^{\prime}$, which are parallel to the chords, are equally inclined to the axis, and therefore $S P$ is equal to $S P^{\prime}$.

Hence

$$
O Q . O Q^{\prime}=O R . O R^{\prime},
$$

and therefore a circle can be drawn through the points $Q, Q^{\prime}, R, R^{\prime}$.
If the two chords are both perpendicular to the axis, it is obvious that a circle can be drawn through their extremities, and this is the only case in which a circle can be drawn through the extremities of parallel chords.

## EXAMPLES.

1. Find the locus of the centre of a circle which passes through a given point and touches a given straight line.
2. Draw a tangent to a parabola, making a given angle with the axis.
3. If the tangent at $P$ meet the tangent at the vertex in $Y$,

$$
A Y^{2}=A S . A N .
$$

4. If the normal at $P$ meet the axis in $G$, the focus is equidistant from the tangent at $P$ and the straight line through $G$ parallel to the tangent.
5. Given the focus, the position of the axis, and a tangent, construct the parabola.
6. Find the locus of the centre of a circle which touches a given straight line and a given circle.
7. Construct a parabola which has a given focus, and two given tangents.
8. The distance of any point on a parabola from the focus is equal to the length of the ordinate at that point produced to meet the tangent at the end of the latus rectum.
9. $P T$ being the tangent at $P$, meeting the axis in $T$, and $P N$ the ordinate, prove that $T Y . T P=T S . T N$.
10. If $S E$ be the perpendicular from the focus on the normal at $P$, shew that

$$
S E^{2}=A N \cdot S P
$$

11. The locus of the vertices of all parabolas, which have a common focus and a common tangent, is a circle.
12. Having given the focus, the length of the latus rectum, and a tangent, construct the parabola.
13. If $P S P^{\prime}$ be a focal chord, and $P N, P^{\prime} N^{\prime}$ the ordinates, shew that

$$
A N . A N^{\prime}=A S^{2}
$$

Shew also that the latus rectum is a mean proportional between the double ordinates.
14. The locus of the middle points of the focal chords of a parabola is another parabola.
15. Shew that in general two parabolas can be drawn having a given straight line for directrix, and passing through two given points on the same side of the line.
16. $\quad P p$ is a chord perpendicular to the axis, and the perpendicular from $p$ on the tangent at $P$ meets the diameter through $P$ in $R$; prove that $R P$ is equal to the latus rectum, and find the locus of $R$.
17. Having given the focus, describe a parabola passing through two given points.
18. The circle on any focal distance as diameter touches the tangent at the vertex.
19. The circle on any focal chord as diameter touches the directrix.
20. A point moves so that its shortest distance from a given circle is equal to its distance from a given diameter of the circle; prove that the locus is a parabola, the focus of which coincides with the centre of the circle,
21. Find the locus of a point which moves so that its shortest distance from a given circle is equal to its distance from a given straight line.
22. If $A P C$ be a sector of a circle, of which the radius $C A$ is fixed, and a circle be described, touching the radii $C A$, $C P$, and the arc $A P$, the locus of the centre of this circle is a parabola.
23. If from the focus $S$ of a parabola, $S Y, S Z$ be perpendiculars drawn to the tangent and normal at any point, $Y Z$ is paraliel to the diameter.
24. Prove that the locus of the foot of the perpendicular from the focus on the normal is a parabola.
25. If $P G$ be the normal, and $G L$ the perpendicular from $G$ upon $S P$, prove that $G L$ is equal to the ordinate $P N$.
26. Given the focus, a point $P$ on the curve, and the length of the perpendicular from the focus on the tangent at $P$, find the vertex.
27. A circle is described on the latus rectum as diameter, and a common tangent $Q P$ is drawn to it and the parabola: shew that $S P, S Q$ make equal angles with the latus rectum.
28. $G$ is the foot of the normal at a point $P$ of the parabola, $Q$ is the middle point of $S G$, and $X$ is the foot of the directrix : prove that

$$
Q X^{2}-Q P^{2}=4 A S^{2} .
$$

29. If $P G$ the normal at $P$ meet the axis in $G$, and if $P F$, $P H$, lines equally inclined to $P G$, meet the axis in $F$ and $H$, the length $S G$ is a mean proportional between $S F$ and $S H$.
30. A triangle $A B C$ circumscribes a parabola whose focus is $S$, and through $A, B, C$, lines are drawn respectively perpendicular to $S A, S B, S C$; shew that these pass through one point.
31. If $P Q$ be the normal at $P$ meeting the curve in $Q$, and if the chord $P R$ be drawn so that $P R, P Q$ are equally inclined to the axis, $P R Q$ is a right angle.
32. $P N$ is a semi-ordinate of a parabola, and $A M$ is taken on the other side of the vertex along the axis equal to $A N$; from any point $Q$ in $P N, Q R$ is drawn parallel to the axis meeting the curve in $R$; prove that the lines $M R, A Q$ will intersect in the parabola.
33. Having given two points of a parabola, the direction of the axis, and the tangent at one of the points, construct the parabola.
34. Having given the vertex of a diameter, and a corresponding double ordinate, construct the parabola.
35. $P M$ is an ordinate of a point $P$; a straight line parallel to the axis bisects $P M$, and meets the curve in $Q ; M Q$ meets the tangent at the vertex in $T$; prove that $3 A T=2 P M$.
36. $A B, C D$ are two parallel straight lines given in position, and $A C$ is perpendicular to both, $A$ and $C$ being given points; in $C D$ any point $Q$ is taken, and in $A Q$, produced if necessary, a point $P$ is taken, such that the distance of $P$ from $A B$ is equal to $C Q$; prove that the locus of $P$ is a parabola.
37. If the tangent and normal at a point $P$ of a parabola meet the tangent at the vertex in $K$ and $L$ respectively, prove that

$$
K L^{2}: S P^{2}:: S P-A S: A S
$$

38. Having given the length of a focal chord, find its position.
39. If the ordinate of a point $P$ bisects the subnormal of a point $P^{\prime}$, prove that the ordinate of $P$ is equal to the normal of $P^{\prime}$.
40. A parabola being traced on a plane, find its axis and vertex.
41. If $P V, P^{\prime} V^{\prime}$ be two diameters, and $P V^{\prime}, P^{\prime} V$ ordinates to these diameters,

$$
P V=P^{\prime} V^{\prime} .
$$

42. If one side of a triangle be parallel to the axis of a parabola, the other sides will be in the ratio of the tangents parallel to them.
43. If $P S p, Q S q$ be focal chords,

$$
P S . S p: Q S . S q:: P p: Q q .
$$

44. $Q V Q^{\prime}$ is an ordinate of a diameter $P V$, and any chord $P R$ meets $Q Q^{\prime}$ in $N$, and the diameter through $Q$ in $L$; prove that

$$
P L^{2}=P N . P R
$$

45. Describe a parabola passing through three given points, and having its axis parallel to a given line.
46. If $A P, A Q$ be two chords drawn from the vertex at right angles to each other, and $P N, Q M$ be ordinates, the latus rectum is a mean proportional between $A N$ and $A M$.
47. $P S p$ is a focal chord of a parabola; prove that $A P, A p$ meet the latus rectum in two points whose distances from the focus are equal to the ordinates of $p$ and $P$ respectively.
48. A chord $P Q$ of a parabola is normal to the parabola at $P$, and the angle $P S Q$ is a right angle ; shew that $S Q=2 S P$.
49. From any point $Q$ in the line $B Q$ which is perpendicular to the axis $C A B$ of a parabola, vertex $A, Q R$ is drawn parallel to the axis to meet the curve in $R$; prove that if $C A$ be equal to $\Delta B$, the lines $A Q, C R$ will meet on the parabola.
50. From the vertex of a parabola a perpendicular is drawn on the tangent at any point ; prove that the locus of its intersection with the diameter through the point is a straight line.
51. If two tangents to a parabola be drawn from any point in its axis, and if any other tangent intersect these two in $P$ and $Q$, prove that $S P=S Q$.
52. $\quad T$ is a point on the tangent at $P$, such that the perpendicular from $T$ on $S P$ is of constant length; prove that the locus of $T$ is a parabola.

If the constant length be $2 A S$, prove that the vertex of the locus is on the directrix.
53. Given a chord of a parabola in magnitude and position; and the point in which the axis cuts the chord, the locus of the vertex is a circle.
54. If the normal at a point $P$ of a parabola meet the curve in $Q$, and the tangents at $P$ and $Q$ intersect in $T$, prove that $T$ and $P$ are equidistant from the directrix.
55. If $T P, T Q$ be tangents to a parabola, such that the chord $P Q$ is normal at $P$,

$$
P Q: P T:: P N: A N,
$$

$P N$ and $A N$ being the ordinate and abscissa.
56. If two equal tangents to a parabola be cut by a third tangent, the alternate segments of the two tangents will be equal.
57. If $A P$ be a chord through the vertex, and if $P L$, perpendicular to $A P$, and $P G$, the normal at $P$, meet the axis in $L, G$ respectively, $G L=$ half the latus rectum.
58. If $P S Q$ be a focal chord, $A$ the vertex, and $P A, Q A$ be produced to meet the directrix in $P^{\prime}, Q^{\prime}$ respectively, then $P^{\prime} S Q^{\prime}$ will be a right angle.
59. The tangents at $P$ and $Q$ intersect in $T$, and the tangent at $R$ intersects $T P$ and $T Q$ in $C$ and $D$; prove that

$$
P C: C T:: C R: R D:: T D: D Q .
$$

60. From any point $D$ in the latus rectum of a parabola, a straight line $D P$ is drawn, parallel to the axis, to meet the curve in $P$; if $X$ be the foot of the directrix, and $A$ the vertex, prove that $A D, X P$ intersect in the parabola.
61. $P S p$ is a focal chord, and upon $P S$ and $p S$ as diameters circles are described; prove that the length of either of their common tangents is a mean proportional between $A S$ and $P p$.
62. If $A Q$ be a chord of a parabola through the vertex $A$, and $Q R$ be drawn perpendicular to $A Q$ to meet the axis in $R$; prove that $A R$ will be equal to the chord through the focus parallel to $A Q$.
63. If from any point $P$ of a circle, $P C$ be drawn to the centre $C$, and a chord $P Q$ be drawn parallel to the diameter $A B$, and bisected in $R$; shew that the locus of the intersection of $C P$ and $A R$ is a parabola.
64. A circle, the diameter of which is three-fourths of the latus rectum, is described about the vertex $A$ of a parabola as centre ; prove that the common chord bisects $A S$.
65. Shew that straight lines drawn perpendicular to the tangents of a parabola through the points where they meet a given fixed line perpendicular to the axis are in general tangents to a confocal parabola.
66. If $Q R$ be a double ordinate, and $P D$ a straight line drawn parallel to the axis from any point $P$ of the curve, and meeting $Q R$ in $D$, prove, from Art. 25, that

$$
Q D \cdot R D=4 A S . P D .
$$

67. Prove, by help of the preceding theorem, that, if $Q Q^{\prime}$ be a chord parallel to the tangent at $P, Q Q^{\prime}$ is bisected by $P D$, and hence determine the locus of the middle point of a series of parallel chords.
68. If a parabola touch the sides of an equilateral triangle, the focal distance of any vertex of the triangle passes through the point of contact of the opposite side.
69. Find the locus of the foci of the parabolas which have a common vertex and a common tangent.
70. From the points where the normals to a parabola meet the axis, lines are drawn perpendicular to the normals: shew that these lines will be tangents to an equal parabola.
71. Inscribe in a given parabola a triangle having its sides parallel to three given straight lines.
72. $P N P^{\prime}$ is a double ordinate, and through a point of the parabola $R Q L$ is drawn perpendicular to $P P^{\prime}$ and meeting $P A$, or $P A$ produced in $R$; prove that

$$
P N: N L:: L R: R Q .
$$

73. $P N P^{\prime}$ is a double ordinate, and through $R$, a point in the tangent at $P, R Q M$ is drawn perpendicular to $P P^{\prime}$ and meeting the curve in $Q$; prove that

$$
Q M: Q R:: P^{\prime} M: P M .
$$

74. If from the point of contact of a tangent to a parabola, a chord be drawn, and a line parallel to the axis meeting the chord, the tangent, and the curve, shew that this line will be divided by them in the same ratio as it divides the chord.
75. $P S p$ is a focal chord of a parabola, $R D$ is the directrix meeting the axis in $D, Q$ is any point in the curve; prove that if $Q P, Q p$ produced meet the directrix in $R, r$, half the latus rectum will be a:mean proportional between $D R$ and $D r$.
76. A chord of a parabola is drawn parallel to a given straight line, and on this chord as diameter a circle is described; prove that the distance between the middle points of this chord, and of the chord joining the other two points of intersection of the circle and parabola, will be of constant length.
77. If a circle and a parabola have a common tangent at $P$, and intersect in $Q$ and $R$; and if $Q V, U R$ be drawn parallel to the axis of the parabola meeting the circle in $V$ and $U$ respectively, then will $V U$ be parallel to the tangent at $P$.
78. If $P V$ be the diameter through any point $P, Q V$ a semiordinate, $Q^{\prime}$ another point in the curve, and $Q^{\prime} P \operatorname{cut} Q V$ in $R$, and $Q^{\prime} R^{\prime}$ the diameter through $Q^{\prime}$ meet $Q V$ in $R^{\prime}$, then

$$
V R . V R^{\prime}=Q V^{2} .
$$

79. $P Q, P R$ are any two chords; $P Q$ meets the diameter through $R$ in the point $F$, and $P R$ meets the diameter through $Q$ in $E$; prove that $E F$ is parallel to the tangent at $P$.
80. If parallel chords be intersected by a diameter, the distances of the points of intersection from the vertex of the diameter are in the ratio of the rectangles contained by the segments of the chords.
81. If tangents be drawn to a parabola from any point $P$ in the latus rectum, and if $Q, Q^{\prime}$ be the points of contact, the semilatus rectum is a geometric mean between the ordinates of $Q$ and $Q^{\prime}$, and the distance of $P$ from the axis is an arithmetic mean between the same ordinates.
82. If $A^{\prime}, B^{\prime}, C^{\prime}$ be the middle points of the sides of a triangle $A B C$, and a parabola drawn through $A^{\prime}, B^{\prime}, C^{\prime}$ meet the sides again in $A^{\prime \prime}, B^{\prime \prime}, C^{\prime \prime}$, then will the lines $A A^{\prime \prime}, B B^{\prime \prime}, C C^{\prime \prime}$ be parallel to each other.
83. A circle passing through the focus cuts the parabola in two points. Prove that the angle between the tangents to the circle at those points is four times the angle between the tangents to the parabola at the same points.
84. The locus of the points of intersection of normals at the extremities of focal chords of a parabola is another parabola.
85. Having given the vertex, a tangent, and its point of contact, construct the parabola.
86. $P S p$ is a focal chord of a parabola ; shew that the distance of the point of intersection of the normals at $P$ and $p$ from the directrix varies as the rectangle contained by $P S, p S$.
87. $T P, T Q$ are tangents to a parabola at $P$ and $Q$, and $O$ is the centre of the circle circumscribing $P T Q$; prove that $T S O$ is a right angle.
88. $P$ is any point of a parabola whose vertex is $A$, and through the focus $S$ the chord $Q S Q^{\prime}$ is drawn parallel to $A P$; $P N, Q M, Q^{\prime} M^{\prime}$, being perpendicular to the axis, shew that $S M$ is a mean proportional between $A M, A N$, and that

$$
M M^{\prime}=A P .
$$

89. If a circle cut a parabola in four points, two on one side of the axis, and two on the other, the sum of the ordinates of the first two is equal to the sum of the ordinates of the other two points.

Extend this theorem to the case in which three of the points are on one side of the axis and one on the other.
90. The tangents at $P$ and $Q$ meet in $T$, and $T L$ is the perpendicular from $T$ on the axis; prove that if $P V, Q M$ be the ordinates of $P$ and $Q$,

$$
P N . Q M=4 A S \cdot A L
$$

91. The tangents at $P$ and $Q$ meet in $T$, and the lines $T A$, $P A, Q A$, meet the directrix in $t, p$, and $q:$ prove that

$$
t p=t q
$$

92. From a point $T$ tangents $T P, T Q$ are drawn, to a parabola, and through $T$ straight lines are drawn parallel to the normal at $P$ and $Q$ : prove that one diagonal of the parallelogram so formed passes through the focus.
93. The chord $P Q$ is normal at $P$, and the tingents at $P$ and $Q$ meet in $T$; prove that the straight line drawn from $S$ at right angles to $S T$ bisects $Q T$.
94. Through a given point within a parabola draw a chord which shall be divided in a given ratio at that point.
95. $A B C$ is a portion of a parabola bounded by the axis $A B$ and the semi-ordinate $B C$ : find the point $P$ in the semi-ordinate such that if $P Q$ be drawn parallel to the axis to meet the parabola in $Q$, the sum of $B P$ and $P Q$ shall be the greatest possible.
96. The diameter through a point $P$ of $\Omega$ parabola meets the tangent at the vertex in $Z$; the normal at $P$ and the focal distance of $Z$ will intersect in a point at the same distance from the tangent at the vertex as $P$.
97. Given a tangent to a parabola and a point on the curve, shew that the foot of the ordinate of the point of contact of the tangent drawn to the diameter through the given point lies on a fixed straight line.
98. Find a point such that the tangents from it to a parabola and the lines from the focus to the points of contact may form a parallelogram.
99. Two equal parabolas have a common focus; and, from any point in the common tangent, another tangent is drawn to each; prove that these tangents are equidistant from the common focus.
100. Two parabolas have a common axis and vertex, and their concavities turned in opposite directions; the latus rectum of one is eight times that of the other ; prove that the portion of a tangent to the former, intercepted between the oommon tangent and axis, is bisected by the latter.

## CHAPTER III.

## THE ELLIPSE.

Def. An ellipse is the curve traced out by a point which moves in such a manner that its distance from a given point is in a constant ratio of less inequality to its distance from a given straight line.

## Tracing the Curve.

51. Let $S$ be the focus, $E X$ the directrix, and $S X$ the perpendicular on $E X$ from $S$.

Divide $S X$ at the point $A$ in the given ratio ; the point $A$ is the vertex.

From any point $E$ in $E X$, draw $E A P, E S L$, and through $S$ draw $S P$ making the angle $P S L$ equal to $L S N$, and meeting EAP in $P$.

Through $P$ draw $L P K$ perpendicular to the directrix and meeting $E S L$ in $L$.
'Then the angle $P S L=L S N=S L P$,

$$
\therefore S P=P I .
$$

Also $P L: P K: S A: A X$.
Hence $S P: P K: S A: A X$,
and $P$ is therefore a point in the curve.
Again, in the axis $X A N$ find a point $A^{\prime}$ such that

$$
S A^{\prime}: A^{\prime} X:: S A: A X ;
$$

this point is evidently on the same side of the directrix as the point $A$, and is another vertex of the curve.

Join $E A^{\prime}$ meeting $P S$ produced in $P^{\prime}$, and draw $P^{\prime} L^{\prime} K^{\prime}$ perpendicular to the directrix and meeting $E S$ in $L^{\prime}$.

Then

$$
\begin{aligned}
P^{\prime} L^{\prime}: P^{\prime} K^{\prime} & :: S A^{\prime}: A^{\prime} X \\
& :: S A: A X,
\end{aligned}
$$

and the angle

$$
S L^{\prime} P^{\prime}=L^{\prime} S A=L^{\prime} S P^{\prime} ;
$$

$$
\therefore P^{\prime} L^{\prime}=S P^{\prime} .
$$

Hence $P^{\prime}$ is also a point in the curve, and $P S P^{\prime}$ is a focal chord.

By giving $E$ a series of positions on the directrix we shall obtain a series of focal chords, and we can also, as in Art. (1), find other points of the curve lying in the lines $K P, K^{\prime} P^{\prime}$, or in these lines produced.

We can thus find any number of points in the curve.
52. Def. The distance $A A^{\prime}$ is the major axis.

The middle point $C$ of $A A^{\prime}$ is called the centre of the ellipse.

If through $C$ the double ordinate $B C B^{\prime}$ be drawn, $B B^{\prime}$ is called the minor axis.

Any straight line drawn through the centre, and terminated by the curve, is called a diameter.

The lines $A C A^{\prime}, B C B^{\prime}$ are called the principal diameters, or, briefly, the axes of the curve.

The line $A C A^{\prime}$ is also sometimes called the transverse axis, and $B C B^{\prime}$ the conjugate axis.
53. Prop. I. If $P$ be any point of an ellipse, and $A A^{\prime}$ the axis major, and if $P A, A^{\prime} P$, when produced, meet the directrix in $E$ and $F$, the distance $E F$ subtends a right angle at the focus.

Draw $P L K$ perpendicular to the directrix, meeting $S F$ in $L$, and the directrix in $K$.

Then

$$
\begin{aligned}
P L: P K & :: S A^{\prime}: A^{\prime} X \\
& :: S P: P K ; \\
\therefore P L & =S P,
\end{aligned}
$$

and the angle $\quad L S P=P L S=L S X$,
that is, $F S$ bisects the angle $A S P$.
But, if $P S$ be produced to $P^{\prime}, E S$ bisects the angle ASP';
$\therefore E S F$ is a right angle.
54. By help of the preceding theorem we shall now prove the existence of another focus and directrix corresponding to the vertex $A$.

In $A A^{\prime}$ produced take a point $X^{\prime}$ such that $A^{\prime} X^{\prime}=A X$, and in $A A^{\prime}$ take a point $S^{\prime \prime}$ such that $A^{\prime} S^{\prime \prime}=A S$.

Through $X^{\prime}$ draw a straight line $e X^{\prime} f$ perpendicular to the axis and let $E P, F P$ produced meet this line in $e$ and $f$. Join $e S^{\prime}$, and $f S^{\prime \prime}$.

Then

$$
\begin{aligned}
e X^{\prime}: E X & :: A X^{\prime}: A X \\
& :: A^{\prime} X: A^{\prime} X^{\prime} \\
& :: F X: f X^{\prime}
\end{aligned}
$$

$\therefore e X^{\prime} \cdot f X^{\prime}=E X . F X=S X^{2}=S^{\prime \prime} X^{\prime 2}$.

Hence $e S^{\prime} f$ is a right angle.
Through $P$ draw $K P k$ parallel to the axis, meeting $e S^{\prime}$ and $f S^{\prime}$ produced in $L$ and $l$.

Then

$$
P L: P k:: S^{\prime} A: A X^{\prime},
$$

and

$$
\begin{gathered}
P l: P k:: S^{\prime \prime} A^{\prime}: A^{\prime} X^{\prime} ; \\
\therefore P L=P l .
\end{gathered}
$$

Moreover, $L S^{\prime} l$ being a right angle,

$$
\begin{gathered}
S^{\prime} P=P l \\
\therefore S^{\prime} P: P k:: S^{\prime} A^{\prime}: A^{\prime} X^{\prime},
\end{gathered}
$$

and the curve can be described by means of the focus $S^{\prime \prime}$ and the directrix $e X^{\prime}$.

Hence also it follows that the curve is symmetrical with regard to $B C B^{\prime}$, and that it lies wholly between the tangents at $A$ and $A^{\prime}$.

If $S A$ be equal to $A X$, the point $A^{\prime}$, and therefore the points $S^{\prime}$ and $X^{\prime}$ will be at an infinite distance from $S$ and $A$.

Hence a parabola is the limiting form of an ellipse, the axis major of which is indefinitely increased in magnitude, while the distance $S A$ remains finite.
55. Prop. II. If $P N$ be the ordinate of any point $P$ of an ellipse, $A C A^{\prime}$ the axis major, and $B C B^{\prime}$ the axis minor,

$$
P N^{2}: A N . N A^{\prime}:: B C^{2}: A C^{2} .
$$

Join $P A, A^{\prime} P$, and let these lines produced meet the directrix in $E$ and $F$.

$$
\begin{aligned}
\text { Then, } & P N: A N:: E X: A X, \\
\text { and } & P N: A^{\prime} N:: F X: A^{\prime} X ;
\end{aligned}
$$

$\therefore P N^{2}: A N . N A^{\prime}:: E X . F X: A X . A^{\prime} X$
:: $S X^{2}: A X . A^{\prime} X$,
since $E S F$ is a right angle (Prop. r.); that is, $P N^{2}$ is to $A N . N A^{\prime}$ in a constant ratio.

Hence, taking $P N$ coincident with $B C$, in which case

$$
\begin{gathered}
A N=N A^{\prime}=A C \\
B C^{2}: A C^{2}: S X^{2}: A X \cdot A^{\prime} X,
\end{gathered}
$$

and $\quad \therefore P N^{2}: A N . N A^{\prime}: B C^{2}: A C^{2}$.

This may be also written

$$
P N^{2}: A C^{2}-C N^{2}:: B C^{2}: A C^{2}
$$

Cor. If $P M$ be the perpendicular from $P$ on the axis minor,

$$
C M=P N, P M=C N,
$$

and $C M^{2}: A C^{2}-P M^{2}:: B C^{2}: A C^{2}$.

Hence $A C^{2}: A C^{2}-P M^{2}:: B C^{2}: C M^{2}$,
and $\therefore A C^{2}: P M^{2}:: B C^{2}: B C^{2}-C M^{2}$,
or

$$
P M^{2}: B M . M B^{\prime}:: A C^{2}: B C^{2} .
$$

56. Conversely, if a point $P$ move in such a manner that $P N^{2}$ is to $A N . N A^{\prime}$ in a constant ratio, $P N$ being the distance of $P$ from the line joining two fixed points $A, A^{\prime}$, and $N$ being between $A$ and $A^{\prime}$, the locus of $P$ will be an ellipse of which $A A^{\prime}$ is the axis.

For, taking $C$ as the middle point of $A A^{\prime}$, draw $B C$ at right angles to $A A^{\prime}$, and such that $B C^{2}$ is to $A C^{2}$ in the given constant ratio; then, if any point $N$ be taken in $A A^{\prime}$, the corresponding point of the locus evidently coincides with a point of the ellipse of which $A C$ and $B C$ are the semi-axes.

It will be shewn in the Appendix that the definition of an ellipse is a property directly deducible from the relation

$$
P N^{2}: A N . N A^{\prime}:: B C^{2}: A C^{2}
$$

57. Prop. III. If $A C A^{\prime}$ be the axis major, $C$ the centre, $S$ one of the foci, and $X$ the foot of the directrix,

$$
C S: C A:: C A: C X:: S A: A X
$$

and $\quad C S: C X: C S^{2}: C A^{2}$.

For

$$
\begin{aligned}
S^{\prime} A: S A & :: A X^{\prime}: A X \\
& :: A^{\prime} X: A X
\end{aligned}
$$

$$
\therefore S S^{\prime}: S A:: A A^{\prime}: A X
$$

or

$$
C S: C A:: S A \quad: A X
$$

Again, $\quad S A^{\prime}: S^{Y} A:: A X^{\prime}: A X ;$

$$
\therefore A A^{\prime}: S A:: X X^{\prime}: A X
$$

or

$$
C A: C X:: S A: A X
$$

$$
\therefore C S: C A:: C A: C X
$$

or

$$
C S . C X=C A^{2}
$$

Also

$$
\begin{aligned}
C S: C X & :: C S^{2}: C S . C X \\
& :: C S^{y}: C A^{2}
\end{aligned}
$$

58. Prop. IV. If' $S$ be a focus, and $B$ an extremity of the axis minor,

$$
S B=A C \text { and } B C^{2}=A S . S A^{\prime}
$$

For, joining $S B$ in the figure of Art. 55,

$$
\begin{aligned}
S B: C X & :: S A: A X \\
& :: C A: C X,
\end{aligned}
$$

by the previous Article,

$$
\therefore S B=C A \text {. }
$$

Also

$$
\begin{aligned}
B C^{2}=S B^{2}-S C^{2} & =A C^{2}-S C^{2} \\
& =A S \cdot S A^{\prime} .
\end{aligned}
$$

59. Prop. V. The semi-latus rectum $S R$ is a third proportional to $A C$ and $B C$.

For, Prop. II.,

$$
\begin{gathered}
S R^{2}: A S \cdot S A^{\prime}:: B C^{2}: A C^{2} \\
: S R^{2}: B C^{2}:: B C^{2}: A C^{2} \\
S R: B C:: B C: A C .
\end{gathered}
$$

or
Cor. Since $S R: S X: S A: A X$

$$
:: S C: A C,
$$

it follows that $S X . S C=S R . A C=B C^{2}$;
and hence also that

$$
S X: C X:: B C^{2}: A C^{2} .
$$

60. Prop. VI. The sum of the focal distances of any point is equal to the axis major.

Let $P N$ be the ordinate of a point $P$ (Fig. Art. 54), then
or

$$
\begin{aligned}
S^{\prime \prime} P: S P & :: N X^{\prime}: N X \\
\therefore S^{\prime} P+S P: S P & :: X X^{\prime}: N X, \\
S^{\prime} P+S P: X X^{\prime} & : S P: N X \\
& :: S A: A X \\
& :: A A^{\prime}: X X^{\prime}
\end{aligned}
$$

$$
\therefore S^{\prime} P+S P=A A^{\prime}
$$

Cor. Since $S P$ : $N X:: S A: A X$
and
Also,

$$
\begin{gathered}
A C-S P: C N:: S A: A X \\
A C-S P=S^{\prime} P-A C
\end{gathered}
$$

$$
\therefore S^{\prime} P-A C: C N:: S A: A X
$$

## Mechanical Construction of the Ellipse.

61. Fasten the ends of a piece of thread to two pins fixed on a board, and trace a curve on the board with a pencil pressed against the thread so as to keep it stretched; the curve traced out will be an ellipse, having its foci at the points where the pins are fixed, and having its major axis equal to the length of the thread.
62. Prop. VII. The sum of the distances of a point from the foci of an ellipse is greater or less than the major axis according as the point is outside or inside the ellipse.

If the point be without the ellipse join $S Q, S^{\prime \prime} Q$, and take a point $P$ on the intercepted arc of the curve.

Then $P$ is within the triangle $S Q S^{\prime \prime}$ and therefore, joining $S P, S^{\prime} P$,

$$
S Q+S^{\prime} Q>S P+S^{\prime} P, \quad \text { Euclid I. } 21 .
$$

i.e. $\quad S Q+S^{\prime} Q>A A^{\prime}$.

$$
\begin{aligned}
& \text { :: } A C: C X \text {; } \\
& \therefore A C: S P: C X: N X, \\
& A C-S P: S P:: C N: N X,
\end{aligned}
$$

If $Q$ be within the ellipse, let $S Q, S^{\prime \prime} Q$ produced mect the curve and take a point $P$ on the intercepted arc.

Then $Q$ is within the triangle $S P S^{\prime \prime}$, and
i.e.

$$
\begin{gathered}
\therefore S P+S^{\prime} P>S Q+S^{\prime} Q, \\
S Q+S^{\prime \prime} Q<A A^{\prime} .
\end{gathered}
$$

63. Def. The circle described on the axis major as diameter is called the auxiliary circle.

Prop. VIII. If the ordinate NP of an ellipse be produced to meet the auxiliary circle in $Q$,

$$
P N: Q N:: B C: A C .
$$

For, Art. 55,

$$
P N^{2}: A N . N A^{\prime}:: B C^{2}: A C^{2}
$$

and, by a property of the circle,

$$
Q N^{2}=A N . N A^{\prime} ;
$$

$\therefore P N: Q N: B C: A C$.
Cor. Similarly, if $P M$ the perpendicular on $B B^{\prime}$ mect in $Q^{\prime}$ the circle described on $B B^{\prime}$ as diameter

$$
P M: Q^{\prime} M:: A C: B C .
$$

For

$$
P M^{2}: B M . M B^{\prime}:: A C^{2}: B C^{2},
$$

and

$$
B M \cdot M B^{\prime}=Q^{\prime} M^{2} .
$$

## Properties of the Tangent and Normal.

64. Prop. IX. The normal at any point bisects the angle between the focal distances of that point, and the tangent is equally inclined to the focal distances.

Let the normal at $P$ meet the axis in $G$; then, Art. 15,
and

$$
\begin{array}{r}
S G: S P:: S A: A X, \\
S^{\prime} G: S^{\prime \prime} P:: S A: A X .
\end{array}
$$

Hence

$$
S G: S^{\prime} G:: S P: S^{\prime} P
$$

and therefore the angle $S P S^{\prime \prime}$ is bisected by $P G$.
Also $F P F^{\prime}$ being the tangent, and $G P F, G P F^{\prime}$ being right angles, it follows that the angles $S P F, S^{\prime} P F^{\prime \prime}$ are equal, or that the tangent is equally inclined to the focal distances.

Hence if $S^{\prime} P$ be produced to $L$, the tangent bisects the angle $S P L$.

Cor. If a circle be described about the triangle $S P S^{\prime \prime}$, its centre will lie in $B C B^{\prime}$, which bisects $S S^{\prime \prime}$ at right angles; and since the angles $S P G, S^{\prime} P G$ are equal, and equal angles stand upon equal arcs, the point $g$, in which $P G$ produced meets the minor axis, is a point in the circle.

Also, if the tangent meet the minor axis in $t$, the point $t$ is on the same circle, since $g P t$ is a right angle.

Hence, Any point $P$ of an ellipse, the two foci, and the points of intersection of the tangent and normal at $P$ with the minor axis lie on the same circle.
65. Prop. X. Every diameter is bisected at the centre and the tangents at the ends of a diameter are parallel.

Let $P C p$ be a diameter, $P N, p n$ the ordinates of $P$ and $p$.

Then $C N^{2}: C n^{2}: P N^{2}: p n^{2}$

$$
:: A C^{2}-C N^{2}: A C^{2}-C n^{2}, \text { Art. } 55
$$

$$
\therefore C N^{2}: A C^{2}:: C n^{2}: A C^{2}
$$

Hence

$$
C N=C n \text { and } \therefore C P=C p .
$$

Draw the focal distances; then, since $P p$ and $S S^{\prime \prime}$ bisect each other in $C$, the figure $S P S^{\prime \prime} p$ is a parallelogram, and the angle

$$
S P S^{\prime \prime}=S p S^{\prime \prime}
$$

But the tangents $P T$, pt are equally inclined to the focal distances;
$\therefore$ the angle $S P T=S^{\prime} p t$,
and, adding the equal angles $C P S, C p S^{\prime \prime}$,

$$
C P T=C p t ;
$$

$\therefore P T$ and $p t$ are parallel.

Cor. Since $S p$ and $S^{\prime} p$ are equally inclined to the tangent at $p$, it follows that $S P$ and $S p$ make equal angles with the tangents at $\boldsymbol{P}$ and $p$.
66. Prop. XI. The perpendiculars from the foci on any tangent meet the tangent on the auxiliary circle, and the semi-minor axis is a mean proportional between their lengths.

Let $S Y, S^{\prime} Y^{\prime}$ be the perpendiculars; join $S^{\prime} P$, and let $S Y, S^{\prime} P$ produced meet in $L$.

The angles $S P Y, Y P L$ being equal, and $P Y$ being common, the triangles are equal in all respects;

$$
\therefore P L=S P, S Y=Y L \text {, }
$$

and

$$
S^{\prime} L=S^{\prime} P+P L=S^{\prime} P+S P=A A^{\prime} .
$$

Join $C Y$, then $C$ being the middle point of $S S^{\prime \prime}$, and $Y$ of $S L, C Y$ is parallel to $S^{\prime} L$,
and

$$
\therefore S^{\prime} L=2 C Y \text {. }
$$

Hence $C Y=A C$, and $Y$ is a point on the auxiliary circle.
Similarly by producing $S P, S^{\prime} Y^{\prime}$ it may be shewn that $Y^{\prime}$ is also on the auxiliary circle.

Let $Y S$ produced meet the circle in $Z$, and join $Y^{\prime} Z$; then $Y^{\prime} Y Z$ being a right angle, $Y^{\prime} Z$ is a diameter and passes through $C$.

Hence the triangles $S C Z, S^{\prime} C Y^{\prime}$ are equal, and

$$
S Y . S^{\prime} Y^{\prime}=S Y . S Z=A S . S A^{\prime}=B C^{2} .
$$

Cor. (1). If $P^{\prime}$ be the other extremity of the diameter through $P$, the tangent at $P^{\prime}$ is parallel to $P Y$, and therefore $Z$ is the foot of the perpendicular from $S$ on the tangent at $P^{\prime}$.

Cor. (2). If the diameter $D C D^{\prime}$, drawn parallel to the tangent at $P$, meet $S P, S^{\prime \prime} P$ in $E$ and $E^{\prime}, P E C Y^{\prime}$ is a parallelogram, for $C Y^{\prime}$ is parallel to $S P$, and $C E$ to $P Y^{\prime}$;
$\therefore P E=C Y^{\prime}=A C$; and similarly $P E^{\prime}=C Y=A C$.
Cor. (3). Any diameter parallel to the focal distance of a point meets the tangent at the point on the auxiliary circle.
67. Prop. XII. To draw tangents from a given point to an ellipse.

For this purpose we may employ the general construction of Art. (14), or the following.

Let $Q$ be the given point; upon $S Q$ as drameter describe a circle cutting the auxiliary circle in $\boldsymbol{Y}$ and $Y^{\prime}$; $Y Q$ and $Y^{\prime} Q$ will be the required tangents.

Producing $S Y$ to $L$ so that $Y L=S Y$, join $S^{\prime} L$ cutting the line $Y Q$ in $P$.

The triangles $S P Y, L P Y$ are equal in all respects, since $S Y=Y L$ and $P Y$ is common and perpendicular to $S L$;

$$
\therefore S P=P L \text { and } S^{\prime} L=S^{\prime} P+P L=S^{\prime} P+S P \text {; }
$$

but, joining $C Y, S^{\prime} L=2 C Y=2 A C$;

$$
\therefore S P+S^{\prime} P=2 A C,
$$

and $P$ is therefore a point on the ellipse.
Also the angle $S P Y=Y P L$, and
$\therefore Q P$ is the tangent at $P$.
A similar construction will give the point of contact of the other tangent $Q P^{\prime}$.

Referring to Art. 31, it will be seen that the construction is the same as that given for the parabola, the ultimate form of the circle being, for the parabola, the tangent at the vertex.
68. Prop. XIII. If two tangents be drawn to an ellipse from an external point, they are equally anclined to the focal distances of that point.

Let $Q P, Q P^{\prime}$ be the tangents, $S Y, S^{\prime} Y^{\prime}, S Z, S^{\prime} Z^{\prime}$ the

perpendiculars from the foci on the tangents; join $Y Z$, $Y^{\prime} Z^{\prime}$.

Then, Art. 66, $\quad S Y \cdot S^{\prime} Y^{\prime}=S Z \cdot S^{\prime} Z^{\prime} ;$

$$
\therefore S Y: S Z:: S^{\prime} Z^{\prime}: S^{\prime} Y^{\prime}
$$

A circle can be drawn through the points $S Y Q Z$, since $S Y Q, S Z Q$ are right angles; and $Y S Z$ and $Y Q Z$ are equal to two right angles, as are also $Y^{\prime} S^{\prime} Z^{\prime}$ and $Y^{\prime} Q Z^{\prime}$; therefore the angle $Y S Z=Y^{\prime} S^{\prime} Z^{\prime}$, and the triangles $Y S Z$, $Y^{\prime} S^{\prime \prime} Z^{\prime}$ are similar.

Hence the angle $S Z Y=S^{\prime} Y^{\prime} Z^{\prime}$.
But $S Z Y=S Q Y$ in the same segment, and similarly

$$
S^{\prime} Y^{\prime} Z^{\prime}=S^{\prime} Q Z^{\prime}
$$

therefore the angle $S Q P=S^{\prime \prime} Q P^{\prime}$.
69. Def. Ellipses which have the same foci are called confocal ellipses.

If $Q$ be a point in a confocal ellipse the normal at $Q$ bisects the angle $S Q S^{\prime}$ and therefore bisects the angle $P Q P^{\prime}$.

Hence, If from any point of an ellipse tangents are drawn to a confocal ellipse, these tangents are equally inclined to the normal at the point.

By reference to the remark of Art. 40 , it will be seen that this theorem includes that of Art. 40 as a particular case.
70. Prop. XIV. If PT the tangent at $P$ meet the axis major in T, and PN be the ordinate,

$$
C N . C T=A C^{2}
$$

Draw the focal distances $S P, S^{\prime \prime} P$, and the perpendicular $S Y$ on the tangent, and join $N Y, C Y$.

Then, as in Art. 66, $C Y$ is parallel to $S^{\prime \prime} P$; therefore the angle

$$
\begin{aligned}
C Y P & =S^{\prime} P t=S P Y \\
& =S N Y
\end{aligned}
$$

since a circle can be drawn through the four points $S Y P N$
Hence

$$
C Y T=C N Y
$$

and the triangles $C Y T, C N Y$ are equiangular.
Therefore $\quad C N: C Y: C Y: C T$
or

$$
C N . C T=C Y^{2}=A C^{2}
$$

Cor. (1). $\quad C N . N T=C N . C T-C N^{2}=A C^{2}-C N^{2}$

$$
=A N \cdot N A^{\prime} .
$$

Cor. (2). Hence it follows that tangents at the extremities of a common ordinate of an ellipse and its auxiliary circle meet the axis in the same point.

For, if $N P$ produced meet the auxiliary circle in $Q$, and the tangent at $Q$ meet the axis in $T^{\prime}$,

$$
C N \cdot C T^{\nu}=C Q^{2}=A C^{2}
$$

therefore $T^{\prime}$ coincides with $T$.

And more generally it is evident that, If any number of ellipses be described having the same major axis, and an ordinate be drawn cutting the ellipses, the tangents at the points of section will all meet the common axis in the same point.
71. Prop. XV. If the tangent at $P$ meet the axis minor in $t$, and $P N$ be the ordinate,

$$
C t . P N=B C^{2}
$$

$$
\begin{aligned}
& \text { For, } \quad C t: P N:: C T: N T, \text { Fig. Art. 70, } \\
& \therefore C t . P N: P N^{2}:: C T . C N: C N . N T \\
& \\
& \quad:: A C^{2}: A N . N A^{\prime} \text {, Cor. 1, Art. 70, } \\
& \\
& \quad:: B C^{2}: P N^{2} . \\
& \therefore C t . P N=B C^{2} .
\end{aligned}
$$

72. Prop. XVI. If the normal at $P$ meet the axes in $G$ and $g$, and the diameter parallel to the tangent at $P$ in $F$,

$$
P F \cdot P G=B C^{2}, \text { and } P F^{\prime} . P g=A C^{2} .
$$

Let $P N, P M$, perpendiculars on the axes, meet the diameter in $K$ and $L$, and let the tangent at $P$ meet the axes in $T$ and $t$.

Then, since a circle can be drawn through GFKN,

$$
P F \cdot P G=P N . P K=P N . C t=B C^{2} .
$$

Similarly, since a circle can be drawn through LMFg,

$$
P F . P g=P M . P L=C N . C T=A C^{2} .
$$

Cor. Since $P G N, P g M$ are similar triangles,
or $\quad N G: C N:: B C^{2}: A C^{2}$,
and $\therefore \quad C G: C N: S C^{2}: A C^{2}$.
Hence also $\quad C G: C N:: S C^{2}: C N . C T$;
$\therefore \quad C G . C T=S C^{2}$.
From Art. 64, cor., it is obvious that

$$
C g . C t=S C^{2}
$$

and it can be easily shewn that

$$
C g: P N:: S C^{2}: B C^{2}
$$

73. Prop. XVII. If PCp be a diameter, and $Q V Q^{\prime}$ a chord parallel to the tangent at $P$ and meeting Pp in $V$, and if the tangent at $Q$ meet $p P$ produced in $T$,

$$
C V . C T=C P^{2} .
$$

Let $T Q$ meet the tangents at $P$ and $p$ in $R$ and $r$, and $S$ being a focus, join $S P, S Q, S p$.

Let fall perpendiculars $R N, R M, r n, r m$ upon these focal distances;
then, since the angle $S P R=S p r$, Cor. Art. (65),
but

$$
\begin{aligned}
R P: r p & :: R N: r n \\
& :: R M: r m, \text { Art. } 13, \\
& :: R Q: r Q ;
\end{aligned}
$$

$$
T R: T r:: R P: r p
$$

$$
\therefore T R: T r:: R Q: r Q .
$$

Hence $T P: T p: P V: V p$,
or

$$
\begin{gathered}
C T-C P: C T+C P:: C P-C V: C P+C V ; \\
\therefore C T: C P:: C P: C V \\
C T \cdot C V
\end{gathered}
$$

or
Cor. 1. Hence, since $C V$ and $C P$ are the same for the point $Q^{\prime}$, the tangent at $Q^{\prime}$ passes through $T$.

Cor. 2. Since $T p: T P:: p V: V P$, it follows that $T P V P$ is harmonically divided.

It will be seen in Chapter X, that this is a particular case of a general theorem.

## Properties of Conjugate Diameters.

74. Prop. XVIII. A diameter bisects all chords parallel to the tangents at its extremities.

We have shewn (Art. 16), that, if $Q Q^{\prime}$ be a chord of a conic, $T Q, T Q^{\prime}$ the tangents at $Q, Q^{\prime}$, and $E P E^{\prime}$ a tangent parallel to $Q Q^{\prime}$, the length $E E^{\prime}$ is bisected at $P$.

Draw the diameter $P C p$; the tangent epe at $p$ is parallel to $E P$, Art. (65), and is therefore parallel to $Q Q^{\prime}$.

Hence $e p=p e^{\prime}$, and $P, p$ being the middle points of the parallels $e e^{\prime}, E E^{\prime}$ the line $P p$ passes through $T$, and moreover bisects $Q Q^{\prime}$.

Similarly, if any other chord $q q^{\prime}$ be drawn parallel to $Q Q^{\prime}$ the tangents at $q$ and $q^{\prime}$ will meet in $p P$ produced, and $q q^{\prime}$ will be bisected by $p P$.

Cor. Hence, if $Q Q^{\prime}, q q^{\prime}$ be two chords parallel to the tangent at $P$, the chords $Q q, Q^{\prime} q^{\prime}$ will meet in $C P$ or $C P$ produced.
75. Def. The diameter DCd, drawn parallel to the tangent at $P$, is said to be conjugate to PCp.

A diameter therefore bisects all chords parallel to its conjugate.

Prop. XIX. If the diameter DCd be conjugate to PCp, then will PCp be conjugate to DCd.

Let the chord $Q V q$ be parallel to $D C d$, and therefore bisected by $P C$, and draw the diameter $q C R$.

Join $Q R$ meeting $C D$ in $U$;
then

$$
R C=C q, \text { and } Q V=V q ;
$$

$\therefore Q R$ is parallel to $C P$

Also

$$
Q U: U R:: q C: C R,
$$

and therefore $Q U=U R$.

That is, $C D$ bisects the chords parallel to $P C p$; therefore $P C p$ is conjugate to $D C d$.

Def. Chords drawn from the extremities of a diameter to any point of the ellipse are called supplemental chords.

Thus $q Q, R Q$ are supplemental chords, and hence it appears that supplemental chords are parallel to conjugate diameters.

Def. A line $Q V$ drawn from a point $Q$ of an ellipse, parallel to the tangent at $P$ and terminated by the diameter PCp, is called an ordinate of that diameter, and QVq is the double ordinate if $Q V$ produced meet the curve in $q$.
76. Any diameter is a mean proportional between the transverse axis and the focal chord parallel to the diameter.

From Art. 66 it follows that if CQT parallel to $P S p$ meet in $T$ the tangent at $P$,

$$
C T=A C .
$$

Draw $P V$ parallel to the tangent at $Q$; then

$$
\begin{gathered}
C V \cdot C T=C Q^{2}, \quad \text { Art. } 73 \\
\therefore P p \cdot A A^{\prime}=Q q^{2} .
\end{gathered}
$$

77. Prop. XX. If $P C p, D C d$ be conjugate diameters, and $Q V$ an ordinate of $P p$,

$$
Q V^{2}: P V . V p:: C D^{2}: C P^{2} .
$$

Let the tangent at $Q$, fig. Art. 75, meet $C P, C D$ produced in $T$ and $t$, and draw $Q U$ parallel to $C P$ and meeting $C D$ in $U$.

Then

$$
\begin{gathered}
C P^{2}=C V \cdot C T \\
C D^{2}=C U . C t=Q V . C t
\end{gathered}
$$

and

$$
\begin{aligned}
\therefore C D^{2}: C P^{2} & :: Q V \cdot C t: C V \cdot C T \\
& : Q V^{2}: C V \cdot V T
\end{aligned}
$$

and

$$
\begin{aligned}
C V \cdot V T & =C V \cdot C T-C V^{2}=C P^{2}-C V^{2} \\
& =P V \cdot V p, \\
\therefore C D^{2} & : C P^{2}:: Q V^{2}: P V \cdot V p
\end{aligned}
$$

78. Prop. XXI. If $A C A^{\prime}, B C B^{\prime}$ be a pair of conjugate diameters, $P C P^{\prime}, D C D^{\prime}$ another pair, and if $P N$, $D M$ be ordinates of $A C A^{\prime}$,

$$
\begin{aligned}
& C N^{2}= A M . M A^{\prime}, \quad C M^{2}=A N . N A, \\
& C M: P N:: A C: B C, \\
& D M: C N:: B C: A C .
\end{aligned}
$$

and

Let the tangents at $P$ and $D$ meet $A C A^{\prime}$ in $T$ and $t$.

Then
hence
$C N . C T=A C^{2}=C M . C t ;$

$$
\begin{aligned}
C M: C N & :: C T: C t \\
& :: P T: C D \\
& : P N: D M \\
& : C N: M t,
\end{aligned}
$$

$$
\therefore C N^{2}=C M . M t=A C^{2}-C M^{2}=A M \cdot M A^{\prime},
$$

and similarly, $\quad C M^{2}=A N . N A^{\prime}$.
Also $D M^{2}: A M . M A^{\prime}: B C^{2}: A C^{2}$,

$$
\therefore D M: C N:: B C: A C,
$$

and similarly $\quad C M: P N:: A C: B C$.
Cor. We have shewn in the course of the proof that

$$
C N^{2}+C M^{2}=A C^{2}
$$

By similar reasoning it appears that if $\boldsymbol{P n}, \mathrm{Dm}$, be ordinates of $B C B^{\prime}$,

$$
\begin{gathered}
C n^{2}+C m^{2}=B C^{2} ; \\
\therefore P N^{2}+D M^{2}=B C^{2} .
\end{gathered}
$$

It should be noticed that these relations are shewn to be true when $A C A^{\prime}, B C B^{\prime}$ are any conjugate diameters, including of course the principal axes.
79. Prop. XXII. If $C P, C D$ be conjugate semi-diameters, and $A C, B C$ the principal semi-diameters,

$$
C P^{2}+C D^{2}=A C^{2}+B C^{2}
$$

From the preceding article,

$$
\begin{aligned}
C N^{2}+C M^{2} & =A C^{2} \\
P N^{2}+D M^{2} & =B C^{2}
\end{aligned}
$$

also $A C B$ being in this case a right angle,

$$
P N^{2}+C N^{2}=C P^{2}
$$

and

$$
D M^{2}+C M^{2}=C D^{2},
$$

$$
\therefore C P^{2}+C D^{2}=A C^{2}+B C^{2}
$$

80. Prop. XXIII. If the normal at $P$ meet the principal axes in $G$ and $g$,
and

$$
\begin{array}{r}
P G: C D:: B C: A C, \\
P g: C D:: A C: B C .
\end{array}
$$

For, the triangles $D C M, P G N$ being similar,

$$
\begin{aligned}
P G & : C D
\end{aligned}:: P N: C M
$$

So also $P g n$ and $D C M$ are similar, and

$$
\begin{aligned}
P g: C D & :: P n: D M \\
& :: A C: B C .
\end{aligned}
$$

81. Prop. XXIV. The parallelogram formed by the tangents at the ends of conjugate diameters is equal to the rectangle contained by the principal axes.

For, taking the preceding figure,
but

$$
P G: B C:: C D: A C \text {; }
$$

$$
\begin{gathered}
P G: B C:: B C: P F, \text { Art. 72, } \\
\therefore C D: A C:: B C: P F, \\
C D \cdot P F=A C . B C,
\end{gathered}
$$

and
whence the theorem stated.
82. Prop. XXV. If $S P, S^{\prime} P$ be the focal distances of $P$, and $C D$ be conjugate to $C P$,

$$
S P \cdot S^{\prime} P=C D^{2}
$$

Let $C D$ meet $S P, S^{\prime} P$ in $E$ and $E^{\prime}$ (fig. Art. 66), and the normal at $P$ in $F$; then $S P Y, P E F$, and $S P Y^{\prime}$ are similar triangles;
and

$$
\therefore S P \cdot S^{\prime} P=C D^{2} .
$$

83. Prop. XXVI. If the tangent at $P$ meet a pair of conjugate diameters in $T$ and $t$, and $C D$ be conjugate to $C P$,

$$
P T . P t=C D^{2} .
$$

From the figure

$$
P T: P N:: C D: D M \text {; }
$$

and, if $T P$ produced meet $C B$ in $t$,

$$
P t: C N:: C D: C M
$$

$\therefore P T . P t: P N . C N:: C D^{2}: D M . C M$.
But

$$
P N . C N=D M . C M, \text { Art. } 78,
$$

$$
\therefore P T . P t=C D^{2} .
$$

$$
\begin{aligned}
& \therefore S P: S Y: P E: P F, \\
& \therefore S P . S^{\prime \prime} P: S Y . S^{\prime} Y^{\prime}:: P E^{2}: P F^{2} \\
& :: A C^{2}: P F^{2} \\
& \text { :: } C D^{2}: B C^{2}, \text { Art. } 81 \text {; }
\end{aligned}
$$

Cor. Let TQU be the tangent at the other end of the chord $P N Q$, meeting $C B^{\prime}$ produced in $U$; and let $C E$ be the semi-diameter parallel to $T Q$.

$$
\begin{gathered}
T P \text { Then }: T Q:: P t: Q U, \\
\therefore T P^{2}: T Q^{2}:: P T \cdot P t: Q T \cdot Q U \\
:: C D^{2}: C E^{2},
\end{gathered}
$$

that is, the two tangents drawn from any point are in the ratio of the parallel diameters.

In a similar manner it can be shewn that, if the tangent at $P$ meet the tangents at the ends of a diameter $A C A^{\prime}$ in $T$ in $T^{\prime \prime}$,

$$
P T \cdot P T^{\prime}=C D^{2}
$$

$C D$ being conjugate to $C P$,
and

$$
A T \cdot A^{\prime} T^{\prime}=C B^{2}
$$

$C B$ being conjugate to $A C A^{\prime}$.
These properties can be demonstrated by the help of Art. 78, and of the corollary to Art. 83.
84. Equi-conjugate diameters.

Prop. XXVII. The diagonals of the rectangle formed by the principal axes are equal and conjugate diameters.

For, joining $A B, A^{\prime} B$, these lines are parallel to the diagonals $C F, C E$; and, $A B, A^{\prime} B$ being supplemental

chords, it follows that $C D, C P$ are conjugate to each other. Moreover, they are equally inclined to the axes, and are therefore of equal length.

Cor. 1. If $Q V, Q U$ be drawn parallel to the equi-conjugate diameters, meeting them in $V$ and $U$,

$$
\begin{aligned}
& Q V^{2}: C P^{2}-C V^{2}:: C D^{2}: C P^{2} ; \\
& \therefore Q V^{2}=C P^{2}-C V^{2}=P V \cdot V P^{\prime},
\end{aligned}
$$

if $P^{\prime}$ be the other end of the diameter $P C P^{\prime}$.
Hence

$$
Q V^{2}+Q U^{2}=C P^{2}
$$

Cor. 2. $\quad C P^{2}+C D^{2}=A C^{2}+B C^{2}$, (Art. 79);

$$
\therefore 2 C P^{2}=A C^{2}+B C^{2}
$$

85. Prop. XXVIII. Pairs of tangents at right angles to each other intersect on a fixed circle.

The two tangents being $T P, T P^{\prime}$, let $S^{\prime \prime} P$ produced meet $S Y$ the perpendicular on $T P$ in $K$.

Then the angle $P T K=S T P=S^{\prime} T P^{\prime}$;
$\therefore S^{\prime \prime} T K$ is a right angle.
Hence

$$
\begin{aligned}
4 A C^{2} & =S^{\prime \prime} K^{2}=S^{\prime \prime} T^{2}+T K^{2} \\
& =S^{\prime} T^{2}+S T^{2} \\
& =2 C T^{2}+2 C S^{2}, \text { Euclid, II. } 12 \text { and } 13 ; \\
\therefore C T^{2} & =A C^{2}+B C^{2},
\end{aligned}
$$

and $T$ lies on a fixed circle, centre $C$.
This circle is called the Director Circle of the Ellipse, and it will be seen that when the ellipse, by the elongation of $S C$ from $S$ is transformed into a parabola, the director circle merges into the directrix of the parabola.
86. Prop. XXIX. The rectangles contained by the segments of any two chords which intersect each other are in the ratio of the squares of the parallel diameters.

Through any point $O$ in a chord $O Q Q^{\prime}$ draw the diameter $O R R^{\prime}$, and let $C D$ be parallel to $Q Q^{\prime}$, and $C P$ conjagate to $C D$, bisecting $Q Q^{\prime}$ in $V$.

Draw $R U$ parallel to $C D$.
Then $C D^{2}-R U^{2}: C U^{2}:: C D^{2}: C P^{2}$, Art. 77,

$$
:: C D^{2}-Q V^{2}: C V^{2}
$$

But $\quad R U^{2}: C U^{2}:: O V^{2}: C V^{2}$;
$\therefore C D^{2}: C U^{2}:: C D^{2}+O V^{2}-Q V^{2}: C V^{2}$

or

$$
\begin{aligned}
C D^{2}: C D^{2}+O V^{2}-Q V^{2} & :: C U^{2}: C V^{2} \\
& :: C R^{2}: C O^{2} ;
\end{aligned}
$$

$\therefore C D^{2}: O V^{2}-Q V^{2}: C R^{2}: C O^{2}-C R^{2}$,
or

$$
C D^{2}: O Q . O Q^{\prime}:=C R^{2}: O R . O R^{\prime} .
$$

Similarly if $O q q^{\prime}$ be any other chord through $O$, and Cd the parallel semi-diameter,

$$
\begin{aligned}
& C d^{2}: O q . O q^{\prime}:: C R^{2}: O R . O R^{\prime} ; \\
& \therefore O Q \cdot O Q^{\prime}: O q \cdot O q^{\prime}:: C D^{2}: C d^{2}
\end{aligned}
$$

This may otherwise be expressed thus,

The ratio of the rectangles of the segments depends only on the directions in which they are drawn.

The proof is the same if the point $O$ be within the ellipse.
87. Prop. XXX. If a circle intersect an ellipse in four points the several pairs of the chords of intersection are equally inclined to the axes.

For if $Q Q^{\prime}, q q^{\prime}$ be a pair of the chords of intersection, and if these meet in $O$, or be produced to meet in $O$, the rectangles $O Q . O Q^{\prime}, O q . O q^{\prime}$ are proportional to the squares on the parallel diameters.

But these rectangles are equal since $Q Q^{\prime}, q q^{\prime}$ are chords of a circle.

Therefore the parallel diameters are equal, and, since equal diameters are equally inclined to the axes, it follows that the chords $Q Q^{\prime}, q q^{\prime}$ are equally inclined to the axes.
88. Conversely, if two chords, not parallel, be equally inclined to the axes a circle can be drawn through their extremities.

For, as in Art. 87, if $O Q Q^{\prime}, O q q^{\prime}$ be two chords, and $C D, C d$ the parallel semi-diameters,

$$
O Q . O Q^{\prime}: O q . O q^{\prime}:: C D^{2}: C d^{2} ;
$$

but, if $C D$ and $C d$ be equally inclined to the axes, they are equal, and

$$
\therefore O Q . O Q^{\prime}=O q . O q^{\prime},
$$

and a circle can be drawn through the points $Q, Q^{\prime}, q$, and $q^{\prime}$.

## EXAMPLES.

1. If the tangent at $B$ meet the latus rectum produced in $D, C D X$ is a right angle.
2. If $P C p$ be a diameter, and the focal distance $p S$ produced meet the tangert at $P$ in $T, S P=S T$.
3. If the normal at $P$ meet the axis minor in $G^{\prime}$ and $G^{\prime} N$ be the perpendicular from $G^{\prime}$ on $S P$, then $P N=A C$.
4. $T Q, T Q^{\prime}$ are two tangents at right angles, and $O T$ meets $Q Q^{\prime}$ in $V$; prove that $V T=Q V$, and, by help of this equality, shew that the locus of $T$ is a circle.
5. The tangent at $P$ bisects any straight line perpendicular to $A A^{\prime}$ and terminated by $A P, A^{\prime} P$, produced if necessary.
6. Draw a tangent to an ellipse parallel to a given line.
7. $S R$ being the semi-latus rectum, if $R A$ meet the directrix in $E$, and $S E$ meet the tangent at $A$ in $T$,

$$
A T=A S
$$

8. Prove that $S Y: S P:: S R: P G$.

Find where the angle $S P S^{\prime}$ is greatest.
9. If two points $E$ and $E^{\prime}$ be taken in the normal $P G$ such that $P E=P E^{\prime}=C D$, the loci of $E$ and $E^{\prime}$ are circles.

Shew that the sum of two conjugate diameters is greater than the sum of the axes, and that their difference is less than the difference of the axes.
10. If from the focus $S^{\prime}$ a line be drawn parallel to $S P$, it will meet the perpendicular $S Y$ in the circumference of a circle.
11. If the normal at $P$ meet the axis major in $G$, prove that $P G$ is an harmonic mean between the perpendiculars from the foci on the tangent at $P$.
12. If tangents $T P, T Q$ be drawn at the extremities $P, Q$ of any focal chord of an ellipse, prove that the angle $P T Q$ is half the supplement of the angle which $P Q$ subtends at the other focus.
13. If $Y, Z$ be the feet of the perpendiculars from the foci on the tangent at $P$; prove that the circle circumscribed about the triangle $Y N Z$ will pass through $C$.
14. If $A Q$ be drawn from one of the vertices perpendicular to the tangent at any point $P$, prove that the locus of the point of intersection of $P S$ and $Q A$ produced will be a circle.
15. If the normal at $P$ meet the axis major in $G$ and the axis minor in $K$, prove that a circle can be drawn through the foci and through the points $P, K$, and that $G K: S K:: S A: A X$, shew also that, if the tangent at $P$ meet the axis minor in $t$,

$$
S t: t K:: B C: C D,
$$

$C D$ being conjugate to $C P$.
16. The straight lines joining each focus to the foot of the perpendicular from the other focus on the tangent at any point meet on the normal at the point and bisect it.
17. If two circles touch each other internally, the locus of the centres of circles touching both is an ellipse whose foci are the centres of the given circles.
18. The subnormal at any point $P$ is a third proportional to the intercept of the tangent at $P$ on the major axis and half the minor axis.
19. If the normal at a point $P$ meet the axis in $G$, and the tangent at $P$ meet the axis in $T$, prove that

$$
T Q: T P:: B C: P G
$$

$Q$ being the point where the ordinate at $P$ meets the auxiliary circle.
20. If the tangent at any point $P$ meet the tangent at the extremities of the axis $A A^{\prime}$ in $F$ and $F^{\prime}$, prove that the rectangle $A F, A^{\prime} F^{\prime}$ is equal to the square on the semiaxis minor.
21. $T P, T Q$ are tangents; prove that a circle can be described with $T$ as centre so as to touch $S P, H P, S Q$, and $H Q$, or these lines produced, $S$ and $H$ being the foci.
22. If two equal and similar ellipses have the same centre, their points of intersection are at the extremities of diameters at right angles to one another.
23. The external angle between any two tangents to an ellipse is equal to the semi-sum of the angles which the chord joining the points of contact subtends at the foci.
24. The tangent at any point $P$ meets the axes in $T$ and $t$; if $S$ be a focus the angles $P S t, S T P$ are equal.
25. $\quad P$ is a point in an ellipse, $P M, P N$ perpendicular to the axes meet respectively when produced the circles described on these axes as diameters in the points $Q, Q_{1}$; shew that $Q Q_{1}$ passes through the centre.
26. If $S Y$ is a perpendicular from the focus $S$ on the tangent at $P$ and $C D$ a diameter conjugate to $C P$,

$$
S Y . C D=S P \cdot B C .
$$

27. A conic is drawn touching an ellipse at the extremities $A, B$ of the axes, and passing through the centre $C$ of the ellipse ; prove that the tangent at $C$ is parallel to $A B$.
28. The tangent at any point $P$ is cut by any two conjugate diameters in $T, t$, and the points $T, t$, are joined with the foci $S$, $H$ respectively; prove that the triangles $S P T, H P t$ are similar to each other.
29. If the diameter conjugate to $C P$ meet $S P$, and $H P$ (or these produced) in $E$ and $E^{\prime}$, prove that $S E$ is equal to $H E^{\prime}$, and that the circles which circumscribe the triangles $S C E, H C E^{\prime}$, are equal to one another.
30. $P G$ is a normal, terminating in the major axis; the circle, of which $P G$ is a diameter, cuts $S P, H P$, in $K, L$, respectively : prove that $K L$ is bisected by $P G$, and is perpendicular to it.
31. $P$ being a point on the curve, the locus of the centre of the circle inscribed in the triangle $S P H$ is an ellipse.
32. Tangents are drawn from any point in a circle through the foci, prove that the lines bisecting the angle between the tangents all pass through a fixed point.
33. If a quadrilateral circumscribe an ellipse, the angles subtended by opposite sides at one of the foci are together equal to two right angles.
34. If the normal at $P$ meet the axis minor in $G$, and if the tangent at $P$ meet the tangent at the vertex $A$ in $V$, shew that $S G: S C:: P V: V A$.
35. $P, Q$ are points in two confocal ellipses, at which the line joining the common foci subtends equal angles; prove that the tangents at $P, Q$ are inclined at an angle which is equal to the angle subtended by $P Q$ at either focus.
36. The transverse axis is the greatest and the conjugate axis the least of all the diameters.
37. If the tangent and ordinate at $P$ meet the transverse axis in $T$ and $N$, prove that any circle passing through $N$ and $T$ will cut the auxiliary circle orthogonally.
38. If $S Y, S^{\prime} Y^{\prime}$ be the perpendiculars from the foci on the tangent at a point $P$, and $P N$ the ordinate, prove that

$$
P Y: P Y^{\prime}:: N Y: N Y^{\prime} .
$$

39. If a circle, passing through $Y$ and $Z$, touch the major axis in $Q$, and that diameter of the circle, which passes through $Q$, meet the tangent in $P$, then $P Q=B C$.
40. From the centre of two concentric circles a straight line is drawn to cut them in $P$ and $Q$; from $P$ and $Q$ straight lines are drawn parallel to two given lines at right angles. Shew that the locus of their point of intersection is an ellipse.
41. From any two points $P, Q$ on an ellipse four hines are drawn to the foci $S, S^{\prime}$ : prove that $S P . S^{\prime} Q$ and $S Q . S^{\prime} P$ are to one another as the squares of the perpendiculars from a focus on the tangents at $P$ and $Q$.
42. Two conjugate diameters are cut by the tangent at any point $P$ in $M, N$; prove that the area of the triangle $C P M$ varies inversely as that of the triangle $C P N$.
43. If $P$ be any point on the curve, and $A V$ be drawn parallel to $P C$ to meet the conjugate $C D$ in $V$, prove that the areas of the triangles $C A V, C P N$ are equal, $P N$ being the ordinate.
44. Two tangents to an ellipse intersect at right angles; prove that the sum of the squares on the chords intercepted on them by the auxiliary circle is constant.
45. Prove that the distance between the two points on the circumference, at which a given chord, not passing through the centre, subtends the greatest and least angles, is equal to the diameter which bisects that chord.
46. The tangeut at $P$ intersects a fixed tangent in $T$; if $S$ is the focus and a line be drawn through $S$ perpendicular to $S T$, meeting the tangent at $P$ in $Q$, shew that the locus of $Q$ is a straight line touching the ellipse.
47. Shew that, if the distance between the foci be greater than the length of the axis minor, there will be four positions of the tangent, for which the area of the triangle, included between it and the straight lines drawn from the centre of the curve to the feet of the perpendiculars from the foci on the tangent, will be the greatest possible.
48. Two ellipses whose axes are equal, each to each, are placed in the same plane with their centres coincident, and axes inclined to each other. Draw their common tangents.
49. An ellipse is inscribed in a triangle, having one focus at the orthocentre; prove that the centre of the ellipse is the centre of the nine-point circle of the triangle and that its transverse axis is equal to the radius of that circle.
50. The tangent at any point $P$ of a circle meets the tangent at a fixed point $A$ in $T$, and $T$ is joined with $B$ the extremity of the diameter passing through $A$; the locus of the point of intersection of $A P, B T$ is an ellipse.
51. If $P G$, the normal at $P$, cut the major axis in $G$, and if $D R, P N$ be the ordinates of $D$ and $P, C D$ being coujugate to $C P$, prove that the triangles $P G N, D R C$ are similar; and thence deduce that $P G$ bears a constant ratio to $C D$.
52. The ordinate $N P$ at a point $P$ meets, when produced, the circle on the major axis in $Q$. If $S$ be a focus of the ellipse, prove that $S Q: S P$ :: the axis major : the chord of the circle through $Q$ and $S$, and that the diameter of the ellipse parallel to $S P$ is equal to the same chord.
53. If the perpendicular from the centre $C$ on the tangent at $P$ meet the focal distance $S P$ produced in $R$, the locus of $R$ is a circle, the diameter of which is equal to the axis major.
54. A perf ectly elastic billiard ball lies on an elliptical billiard table, and is projected in any direction along the table: shew that all the lines in which it moves after each successive impact touch an ellipse or an hyperbola confocal with the billiard table.
55. Shew that a circle can be drawn through the foci and the intersections of any tangent with the tangents at the vertices.
56. If $C P, C D$ be conjugate semi-diameters, and a rectangle be described so as to have $P D$ for a diagonal and its sides parallel to the axes, the other angular points will be situated on two fixed straight lines passing through the centre $C$.
57. If the tangent at $P$ meet the minor axis in $T^{\prime}$, prove that the areas of the triangles $S P S^{\prime}, S T S^{\prime}$ are in the ratio of the squares on $C D$ and $S T$.
58. Find the locus of the centre of the circle touching the transverse axis, $S P$, and $S^{\prime} P$ produced.
59. In an ellipse $S Q$ and $S^{\prime} Q$, drawn perpendicularly to a pair of conjugate diameters, intersect in $Q$; prove that the locus of $Q$ is a concentric ellipse.
60. The distance of any point on the auxiliary circle from the directrix is proportional to the distance of the focus from the tangent at that point.
61. If $C Q$ be conjugate to the normal at $P$, then is $C P$ conjugate to the normal at $Q$.
62. $P Q$ is one side of a parallelogram described about an ellipse, having its sides parallel to conjugate diameters, and the lines joining $P, Q$ to the foci intersect in $D, E$; prove that the points $D, E$ and the foci lie on a circle.
63. If the centre, a tangent, and the transverse axis be given, prove that the directrices pass each through a fixed point.
64. The straight line joining the feet of perpendiculars from the focus on two tangents is at right angles to the line joining the intersection of the tangents with the other focus.
65. A circle passes through a focus, has its centre on the major axis of the ellipse, and touches the ellipse: shew that the straight line from the focus to the point of contact is equal to the latus rectum.
66. Prove that the perimeter of the quadrilateral formed by the tangent, the perpendiculars from the foci, and the transverse axis, will be the greatest possible when the focal distances of the point of contact are at right angles to each other.
67. Given a focus, the length of the transverse axis, and that the second focus lies on a straight line, prove that the ellipse will touch two fixed parabolas having the given focus for focus.
68. From any point on one of the equi-conjugate diameters two tangents are drawn; prove that the circle passing through the point and the two points of contact will also pass through the centre.
69. If $P N$ be the ordinate of $P$, and if with centre $C$ and radius equal to $P N$ a circle be described intersecting $P N$ in $Q$, prove that the locus of $Q$ is an ellipse.
70. If $A Q O$ be drawn parallel to $C P$, meeting the curve in $Q$ and the minor axis in $O, 2 C P^{2}=A O . A Q$.
71. $P S$ is a focal distance; $C R$ is a radius of the auxiliary circle parallel to $P S$, and drawn in the direction from $P$ to $S$; $S Q$ is a perpendicular on $C R$ : shew that the rectangle contained by $S P$ and $Q R$ is equal to the square on half the minor axis.
72. If a focus be joined with the point where the tangent at the nearer vertex intersects any other tangent, and perpendiculars be let fall from the other focus on the joining line and on the last-mentioned tangent, prove that the distance between the feet of these perpendiculars is equal to the distance from eitber focus to the remoter vertex.
73. A parallelogram is described about an ellipse; if two of its angular points lie on the directrices, the other two will lie on the auxiliary circle.
74. From a point in the auxiliary circle straight lines are drawn touching the ellipse in $P$ and $P^{\prime}$; prove that $S P$ is parallel to $S^{\prime} P^{\prime}$.
75. If the tangent and normal at any point meet the axis major in $T$ and $G$ respectively, prove that

$$
C G \cdot C T=C S^{2}
$$

76. Find the locus of the points of contact of tangents to a series of confocal ellipses from a fixed point in the axis major.
77. A series of confocal ellipses intersect a given straight line; prove that the locus of the points of intersection of the pairs of tangents drawn at the extremities of the chords of intersection is a straight line at right angles to the given straight line.
78. Given a focus and the length of the major axis; describe an ellipse touching a given straight line and passing through a given point.
79. Given a focus and the length of the major axis; describe an ellipse touching two given straight lines.
80. Find the positions of the foci and directrices of an ellipse which touches at two given points $P, Q$, two given straight lines $P O, Q O$, and has one focus on the line $P Q$, the angle $P O Q$ being less than a right angle.
81. Through any point $P$ of an ellipse are drawn straight lines $A P Q, A^{\prime} P R$, meeting the auxiliary circle in $Q, R$, and ordinates $Q q, R r$ are drawn to the transverse axis; prove that, $L$ being an extremity of the latus rectum,

$$
A q \cdot A^{\prime} r: A r \cdot A^{\prime} q:: A C^{2}: S L^{2}
$$

82. If a tangent at a point $P$ meet the major axis in $T$, and the perpendiculars from the focus and centre in $Y$ and $Z$, then

$$
T Y^{2}: P Y^{2}:: T Z: P Z
$$

83. An ellipse slides between two lines at right angles to each other; find the locus of its centre.
84. $T P, T Q$ are two tangents, and $C P^{\prime}, C Q^{\prime}$ are the radii from the centre respectively parallel to these tangents, prove that $P^{\prime} Q^{\prime}$ is parallel to $P Q$.
85. The tangent at $P$ meets the minor axis in $t$; prove that

$$
S t \cdot P N=B C \cdot C D
$$

86. If the circle, centre $t$, and radius $t S$, meet the ellipse in $Q$, and $Q M$ be the ordinate, prove that

$$
Q M: P N:: B C: B C+C D .
$$

87. Perpendiculars $S Y, S^{\prime} Y^{\prime}$ are let fall from the foci upon a pair of tangents $T Y, T Y^{\prime}$; prove that the angles $S T Y, S^{\prime} T Y^{\prime}$ are equal to the angles at the base of the triangle $Y C^{\prime} Y^{\prime}$.
88. $P Q$ is the chord of an ellipse normal at $P, L C L^{\prime}$ the diameter bisecting it, shew that $P Q$ bisects the angle $L P L^{\prime}$ and that $L P+P L^{\prime}$ is constant.
89. $A B C$ is an isosceles triangle of which the side, $A B$ is equal to the side $A C$. $B D, B E$ drawn on opposite sides of $B C$ and equally inclined to it meet $A C$ in $D$ and $E$. If an ellipse is described round $B D E$ having its axis minor parallel to $B C$, then $A B$ will be a tangent to the ellipse.
90. If $A$ be the extremity of the major axis and $P$ any point on the curve, the bisectors of the angles $P S A, P S^{\prime} A$ meet on the tangent at $P$.
91. If two ellipses intersect in four points, the diameters parallel to a pair of the chords of intersection are in the same ratio to each other.
92. From any point $P$ of an ellipse a straight line $P Q$ is drawn perpendicular to the focal distance $S P$, and meeting in $Q$ the diameter conjugate to that through $P$; shew that $P Q$ varies inversely as the ordinate of $P$.
93. If a tangent to an ellipse intersect at right angles a tangent to a confocal ellipse, the point of intersection lies on a fixed circle.
94. If a circle be drawn through the foci of two confocal ellipses, cutting the ellipses in $P$ and $Q$, the tangents to the ellipses at $P$ and $Q$ will intersect on the circumference of the same circle.
95. If any two points $P, Q$ be given in an ellipse, prove that a third point $R$ may be found so that the angle $P R Q$ is a maximum by the following construction. Draw a tangent parallel to $P Q$, touching the ellipse in $K$, and draw $K R$ perpendicular to the major axis, cutting the curve again in $R$.
96. Through the middle point of a focal chord a straight line is drawn at right angles to it to meet the axis in $R$; prove that $S R$ bears to $S C$ the duplicate ratio of the chord to the diameter parallel to it, $S$ being the focus and $C$ the centre.
97. The tangent at a point $P$ meets the auxiliary circle in $Q^{\prime}$ to which corresponds $Q$ on the ellipse; prove that the tangent at $Q$ cuts the auxiliary circle in the point corresponding to $P$.
98. If a chord be drawn to a series of concentric, similar, and similarly situated ellipses, and meet one in $P$ and $Q$, and if on $P Q$ as diameter a circle be described meeting that ellipse again in $R S$, shew that $R S$ is constant in position for all the ellipses.
99. An ellipse touches the sides of a triangle ; prove that if one of its foci move along the arc of a circle passing through two of the angular points of the triangle, the other will move along the arc of a circle through the same two angular points.
100. The normal at a point $P$ of an ellipse meets the conjugate axis in $K$, and a circle is described with centre $K$ and passing through the foci $S$ and $H$. The lines $S Q, H Q$, drawn through any point $Q$ of this circle, meet the tangent at $P$ in $T$ and $t$; prove that $T$ and $t$ lie on a pair of conjugate diameters.
101. If $S P, S^{\prime} Q$ be parallel focal distances drawn towards the same parts, the tangents at $P$ and $Q$ intersect on the auxiliary circle.
102. Having given one focus, one tangent and the eccentricity of an ellipse, prove that the locus of the other focus is a circle.
103. $P S Q$ is a focal chord of an ellipse, and $p q$ is any parallel chord; if $P Q$ meet in $T$ the tangent at $p$,

$$
p q: P Q:: S p: S T .
$$

104. If an ellipse be inscribed in a quadrilateral so that one focus is equidistant from the four vertices, the other focus must be at the intersection of the diagonals.
105. If a pair of conjugate diameters of an ellipse be produced to meet either directrix, prove that the orthocentre of the triangle so formed is the corresponding focus of the curve.
106. A pair of conjugate diameters intercept, on the tangent at either vertex, a length which subtends supplementary angles at the foci.

## CHAPTER IV.

## THE HYPERBOLA.

Definition.
An hyperbola is the curve traced by a point which moves in such a manner, that its distance from a given point is in a constant ratio of greater inequality to its distance from a given straight line.

Tracing the Curve.
89. Let $S$ be the focus, $E X$ the directrix, and $A$ the vertex.

Then, as in Art. 2, any number of points on the curve may be obtained by taking successive positions of $\boldsymbol{E}$ on the ${ }^{-}$ directrix.

In $S X$ produced, find a point $A^{\prime}$ such that

$$
S A^{\prime}: A^{\prime} X:: S A: A X,
$$

then $A^{\prime}$ is the other vertex as in the ellipse, and, the eccentricity being greater than unity, the points $A$ and $A^{\prime}$ are evidently on opposite sides of the directrix.

Find the point $P$ corresponding to $E$, and let $A^{\prime} E, P S$ produced meet in $P^{\prime}$, then, if $P^{\prime} K^{\prime}$ perpendicular to the directrix meet $S E$ produced in $L^{\prime}$,

$$
\begin{aligned}
P^{\prime} L^{\prime}: P^{\prime} K^{\prime} & :: S A^{\prime}: A^{\prime} X \\
& :: S A: A X,
\end{aligned}
$$

and the angle

$$
\begin{gathered}
P^{\prime} L^{\prime} S=L^{\prime} S X=L^{\prime} S P^{\prime} ; \\
\therefore S P^{\prime}=P^{\prime} L^{\prime} .
\end{gathered}
$$

Hence $P^{\prime}$ is a point in the curve, and $P S P^{\prime}$ is a focal chord.

Following out the construction, we observe that, since $S A$ is greater than $A X$, there are two points on the directrix, $e$ and $e^{\prime}$, such that $A e$ and $A e^{\prime}$ are each equal to $A S$.

If $E$ coincide with $e$, the angle

$$
Q S L=L S N=A S e=A e S
$$

Hence $S Q, A P$ are parallel, and the corresponding point of the curve is at an infinite distance; and similarly the curve tends to infinity in the direction $A e^{\prime}$.

Further, the angle $A S E$ is less or greater than $A E S$, according as the point $E$ is, or is not, between $e$ and $e^{\prime}$.

Hence, when $E$ is below $e$, the curve lies above the axis, to the right of the directrix ; when between $e$ and $X$, below the axis to the left; when between $X$ and $e^{\prime}$, above the axis to the left ; and when above $e^{\prime}$, below the axis to the right. Hence a general idea can be obtained of the form of the curve, tending to infinity in four directions, as in the figure of Art. 98.

## Definitions.

The line $A A^{\prime}$ is called the transverse axis of the hyperbola.

The middle point, $C$, of $A A^{\prime}$ is the centre.
Any straight line, drawn through $C$, and terminated by the curve is called a diameter.
90. Prop. I. If $P$ be any point of an hyperbola, and $A A^{\prime}$ its transverse axis, and if $A^{\prime} P$, and $P A$ produced, (or $P A$ and $P A^{\prime}$ produced) meet the directrix in $E$ and $F, E F$ subtends a right angle at the focus.

Let $P K L$, perpendicular to the directrix, meet $S F$ produced in $L$.

Then

$$
\begin{aligned}
& P L: S A^{\prime}:: P F: A^{\prime} F \\
&:: P K: A^{\prime} X, \\
& P L: P K: S A^{\prime}: A^{\prime} X ; \\
& \therefore S P=P L,
\end{aligned}
$$

and the angle

$$
L S P=P L S=L S X
$$

Similarly, if $P S$ be produced to $P^{\prime}, E S$ bisects the angle $A S P^{\prime}$;
$\therefore E S F$ is a right angle.
91. We shall now prove the existence of another focus and directrix corresponding to the vertex $A^{\prime}$.

In $A A^{\prime}$ take a point $X^{\prime}$ such that $A^{\prime} X^{\prime}=A X$, and through $X^{\prime}$ draw a straight line perpendicular to $A A^{\prime}$. Also in $S A^{\prime}$ produced, take a point $S^{\prime}$ such that $A^{\prime} S^{\prime}=A S$.

Let $A^{\prime} P$ and $P A$ produced meet the perpendicular through $X^{\prime}$ in $f$ and $e$, and join $S^{\prime} e, S^{\prime} f$.

Then

$$
\begin{gathered}
e X: E X:: A X^{\prime}: A X, \\
\\
:: A^{\prime} X: A^{\prime} X^{\prime}, \\
\\
:: F X: f X^{\prime} ; \\
\therefore e X^{\prime} \cdot f X^{\prime}=E X \cdot F X=S X^{2}=S^{\prime} X^{\prime 2} .
\end{gathered}
$$

Hence $e S^{\prime} f$ is a right angle.
Through $P$ draw $P K G$ parallel to the axis meeting $E X, e X^{\prime}$ in $K, G$, and $e S^{\prime}, S^{\prime} f$ produced in $L$ and $l$;
then
and

$$
\therefore P L=P l \text {; }
$$

and, $L S^{\prime \prime} l$ being a right angle,

$$
\begin{gathered}
S^{\prime} P=P L=P l ; \\
\therefore S^{\prime} P: P G:: S^{\prime} A^{\prime}: A^{\prime} X^{\prime} ;
\end{gathered}
$$

and the curve can be described by means of the focus $S^{\prime \prime}$ and directrix $e X^{\prime}$.

Hence it follows that the curve is symmetrical with regard to the point $C$, and that it lies wholly without the tangents at the vertices $A$ and $A^{\prime}$.
92. Prop. II. If $P N$ be the ordinate of a point $P$, and $A C A^{\prime}$ the transverse axis, $P N^{2}$ is to $A N . N A^{\prime}$ in a constant ratio.

Join $A P, A^{\prime} P$, meeting the directrix in $E$ and $F$, fig. Art. 90.

$$
\begin{aligned}
& \text { Then } \quad P N: A N:: E X: A X, \\
& \text { and } \quad P N: A^{\prime} N:: F X: A^{\prime} X ; \\
& \therefore P N^{2}: A N \cdot N A^{\prime}:: E X \cdot F X: A X \cdot A^{\prime} X \\
&
\end{aligned}
$$

Since $E S F$ is a right angle; that is, $P N^{2}$ is to $A N . N A^{\prime}$, in a constant ratio.

Through $C$, the middle point of $A A^{\prime}$, draw $C B$ at right angles to the axis, and such that

$$
B C^{2}: A C^{2}: S X^{2}: A X \cdot A^{\prime} X
$$

then

$$
P N^{2}: A N . N A^{\prime}:: B C^{2}: A C^{2}
$$

or

$$
P N^{2}: C N^{2}-A C^{2}:: B C^{2}: A C^{2}
$$

Cor. If $P M$ be the perpendicular from $P$ on $B C$,

$$
P M=C N, \text { and } P N=C M
$$

$$
\therefore C M^{2}: P M^{2}-A C^{2}:: B C^{2}: A C^{2}
$$

$$
\begin{aligned}
& P L: P G:: S^{\prime} A: A X^{\prime}, \\
& P l: P G:: S^{\prime \prime} A^{\prime}: A^{\prime} X^{\prime} ;
\end{aligned}
$$

or $C M^{2}: B C^{2}:: P M^{2}-A C^{2}: A C^{2}$; $\therefore C M^{2}+B C^{2}: B C^{2}:: P M^{2}: A C^{2}$,
or

$$
P M^{2}: C M^{2}+B C^{2}:: A C^{2}: B C^{2}
$$

Conversely, if a point $P$ move in such a manner that $P N^{2}$ is to $A N . N A^{\prime}$ in a constant ratio, $P N$ being the distance of $P$ from the line joining two fixed points $A$ and $A^{\prime}$, and $N$ not being between $A$ and $A^{\prime}$, the locus of $P$ is an hyperbola of which $A A^{\prime}$ is the transverse axis.
93. If we describe the circle on $A A^{\prime}$ as diameter, which we may term for convenience, the auxiliary circle, the rectangle $A N . N A^{\prime}$ is equal to the square on the tangent to the circle from $N$.

Hence the preceding theorem may be thus expressed :
The ordinate of an hyperbola is to the tangent from its foot to the auxiliary circle in the ratio of the conjugate to the transverse axis.

Def. If $C B^{\prime}$ be taken equal to $C B$, on the other side of the axis, the line $B C B^{\prime}$ is called the conjugate axis.

The two lines $A A^{\prime}, B B^{\prime}$ are the principal axes of the curve.

When these lines are equal, the hyperbola is said to be equilateral, or rectangular.

The lines $A A^{\prime}, B B^{\prime}$ are sometimes called major and minor axes, but, as $A A^{\prime}$ is not necessarily greater than $B B^{\prime}$, these terms cannot with propriety be generally employed.
94. Prop. III. If $A C A^{\prime}$ be the transverse axis, $C$ the centre, $S$ one of the foci, and $X$ the foot of the directrix,
and

$$
C S: C A:: C A: C X:: S A: A X
$$

$C S: C X: C S^{2}: C A^{2}$.
Interchanging the positions of $S$ and $X$ for a new

| $S^{\prime}$ | $\dot{A}^{\prime}$ | $\dot{X}^{\prime}$ | $\dot{C}$ | $\dot{X}$ | $\dot{A}$ | $S$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

figure, the proof of these relations is identical with the proof given for the ellipse in Art. 57.
95. Prop. IV. If $S$ be a focus, and B an extremity of the conjugate axis.

$$
B C^{2}=A S . S A^{\prime}, \text { and } S C^{2}=A C^{2}+B C^{2}
$$

Referring to Art. (94), $S X=S A+A X$;

$$
\begin{aligned}
\therefore S X: A X & :: S A+A X: A X, \\
& :: S C+A C: A C ;
\end{aligned}
$$

and similarly

$$
S X: A^{\prime} X:: S C-A C: A C ;
$$

$$
\therefore S X^{2}: A X \cdot A^{\prime} X:: S C^{2}-A C^{2}: A C^{2}
$$

But

$$
\begin{aligned}
& B C^{2}: A C^{2}:: S X^{2}: A X . A^{\prime} X \\
& \quad \therefore B C^{2}=S C^{2}-A C^{2}=A S . S A^{\prime} .
\end{aligned}
$$

Hence $S C^{2}=A C^{2}+B C^{2}=A B^{2} ;$
i. e. $S C$ is equal to the line joining the ends of the axes.
96. Prop. V. The difference of the focal distances of any point is equal to the transverse axis.

For, if $P K K^{\prime}$, perpendicular to the directrices, meet them in $K$ and $K^{\prime}$,

$$
S^{\prime \prime} P: P K^{\prime}:: S A: A X
$$

and $S P: P K$ :: $S A: A X ;$ $\therefore S^{\prime} P-S P: K K^{\prime}:: S A: A X$, :: $A A^{\prime}: X X^{\prime}$, Art. 93.
$\therefore S^{\prime \prime} P-S P=A A^{\prime}$.
Cor. 1.

$$
S P: N X:: A C: C X
$$

$\therefore S P: A C:: N X: C X ;$
$\therefore S P+A C: A C: C N: C X$,
or

$$
S P+A C: C N:: S A: A X
$$

Hence also $S^{\prime \prime} P-A C: C N:: S A: A X$.

Cor. 2. Hence also it can be easily shewn, that the difference of the distances of any point from the foci of an hyperbola, is greater or less than the transverse axis, according as the point'is within or without the concave side of the curre.

## 97. Mechanical Construction of the Hyperbola.

Let a straight $\operatorname{rod} S^{\prime} L$ be moveable in the plane of the paper about the point $S^{\prime \prime}$. Take a piece of string, the

length of which is less than that of the rod, and fasten one end to a fixed point $S$, and the other end to $L$, then pressing a pencil against the string so as to keep it stretched, and a part of it $P L$ in contact with the rod, the pencil will trace out on the paper an hyperbola, having its foci at $S$ and $S^{\prime \prime}$, and its transverse axis equal to the difference between the length of the rod and that of the string.

This construction gives the right-hand branch of the curve; to trace the other branch, take the string longer than the rod, and such that it exceeds the length of the rod by the transverse axis.

We may remark that by taking a longer rod $M S^{\prime \prime} L$, and taking the string longer than $S S^{\prime \prime}+S^{\prime} L$, so that the point $P$ will be always on the end $S^{\prime \prime} M$ of the rod, we shall obtain an ellipse of which $S$ and $S^{\prime}$ are the foci. Moreover, remembering that a parabola is the limiting form of an ellipse when one of the foci is removed to an infinite distance, the mechanical construction, given for the parabola, will be seen to be a particular case of the above.

[^0]
## The Asymptote.

98. We have shewn in Art. (89) that if two points, $e$ and $e^{\prime}$, be taken on the directrix such that

$$
A e=A e^{\prime}=A S,
$$

the lines $e A, e^{\prime} A$ meet the curve at an infinite distance.

These lines are parallel to the diagonals of the rectangle formed by the axes, for

$$
\begin{aligned}
A e^{\prime}: A X & :: A S: A X \\
& :: S C: A C, \text { Art. (93), } \\
& :: A B: A C, \text { Art. (95). }
\end{aligned}
$$

Definition. The diagonals of the rectangle formed by the principal axes are called the asymptotes.

We observe that the axes bisect the angles between the asymptotes, and that if a double ordinate, $P N P^{\prime}$, when produced, meet the asymptotes in $Q$ and $Q^{\prime}$,

$$
P Q=P^{\prime} Q^{\prime} .
$$

The figure appended will give the general form of the curve and its connection with the asymptotes and the auxiliary circle.

99. Prop. VI. The asymptotes intersect the directrices in the same points as the auxiliary circle, and the lines joining the corresponding foci with the points of intersection are tangents to the circle.

If the asymptote $C L$ meet the directrix in $D$, joining $S D$, fig. Art. (98), $C L^{2}=A C^{2}+B C^{2}=S C^{2}$, and

$$
\begin{aligned}
C D: C X & :: C L: C A \\
& :: S C: C A \\
& :: C A: C X ;
\end{aligned}
$$

$\therefore C D=C A$, and $D$ is on the auxiliary circle.
Also

$$
C S . C X=C A^{2}=C D^{2} ;
$$

$\therefore C D S$ is a right angle, and $S D$ is the tangent at $D$.
Cor. $\quad C D^{2}+S D^{2}=C S^{2}=A C^{2}+B C^{2}$, Art. 95 ;

$$
\therefore S D=B C .
$$

100. An asymptote may also be characterized as the ultimate position of a tangent when the point of contact is removed to an infinite distance.

It appears from Art. (7) that in order to find the point of contact of a tangent drawn from a point $T$ in the directrix, we must join $T$ with the focus $S$, and draw through $S$ a straight line at right angles to $S T$; this line will meet the curve in the point of contact.

In the figure of Art. (98) we know that the straight line through $S$, parallel to $e A$ or $C L$, meets the curve in a point at an infinite distance, and also that this straight line is at right angles to $S D$, since $S D$ is at right angles to $C D$. Hence the tangent from $D$, that is the line from $D$ to the point at an infinite distance, is perpendicular to $D S$ and therefore coincident with $C D$.

The asymptotes therefore touch the curve at an infinite distance.
101. Def. If an hyperbola be described, having for its transverse and conjugate axes, respectively, the conjugate and transverse axes of a given hyperbola, it is called the conjugate hyperbola.

It is evident from the preceding article that the conjugate hyperbola has the same asymptotes as the original hyperbola, and that the distances of its foci from the ceutre are also the same.

The relations of Art. (92) and its Corollary are also true, mutatis mutandis, of the conjugate hyperbola; thus, in Art. (92), if $P$ be a point in the conjugate hyperbola,

$$
P M^{2}: C M^{2}-B C^{2}:: A C^{2}: B C^{2},
$$

and

$$
C M^{2}: P M^{2}+A C^{2}:: B C^{2}: A C^{2}
$$

Def. A straight line drawn through the centre and terminated by the conjugate hyperbola is also called a diameter of the original hyperbola.
102. Prop. VII. If from any point $Q$ in one of the asymptotes, two straight lines QPN, QRM be drawn at right angles respectively to the transverse and conjugate axes, and meeting the hyperbola in $P, p$, and the conjugate hyperbola in $R, r$,

$$
Q P \cdot Q p=B C^{2},
$$

and

$$
Q R . Q r=A C^{2} .
$$

$$
\begin{aligned}
& \text { For } \begin{aligned}
Q N^{2}: B C^{2} & :: C N^{2}: A C^{2} \\
\therefore Q N^{2}-B C^{2}: B C^{2} & :: C N^{2}-A C^{2}: A C^{2} \\
& :: P N^{2}: B C^{2} ;
\end{aligned}
\end{aligned}
$$

or i. 0.
$\therefore Q N^{2}-B C^{2}=P N^{2}$, $Q N^{2}-P N^{2}=B C^{2} ;$
$Q P . Q p=B C^{2}$.

Similarly, $Q M^{2}: A C^{2}$ :: $C M^{2}: B C^{2}$;

$$
\begin{aligned}
\therefore Q M^{2}-A C^{2}: A C^{2} & :: C M^{2}-B C^{2}: B C^{2} \\
& :: R M^{2}: A C^{2}
\end{aligned}
$$

$$
\therefore Q M^{2}-R M^{2}=A C^{2}
$$

or

$$
Q R \cdot Q r=A C^{2}
$$

These relations may also be given in the form,

$$
Q P \cdot P q=B C^{2}, \quad Q R \cdot R q^{\prime}=A C^{2}
$$

Cor. If the point $Q$ be taken at a greater distance from $C$, the length $Q N$ and therefore $Q p$ will be increased and may be increased indefinitely.

But the rectangle $Q P . Q p$ is of finite magnitude; hence $Q P$ will be indefinitely diminished, and the curve, therefore, as it recedes from the centre, tends more and more nearly to coincidence with the asymptote.

A further illustration is thus given of the remarks in Art. (100).
103. If in the preceding figure the line $Q q$ be produced to meet the conjugate hyperbola in $\boldsymbol{E}$ and $e$, it can be shewn, in the same manner as in Art. (102), that

$$
Q E . Q e=B C^{2} ;
$$

and this equality is still true when the line $Q q$ lies between $C$ and $A$, in which case $Q q$ does not meet the hyperbola.

## Properties of the Tangent and Normal.

104. Prop. VIII. The tangent at any point bisects the angle between the focal distances of that point, and the normal is equally inclined to the focal distances.

Let the normal at $P$ meet the axis in $G$.
Then, Art. (15),
and

$$
\begin{aligned}
& S G: S P:: S A: A X, \\
& S^{\prime} G: S^{\prime} P: S A: A X ; \\
& \therefore S G: S^{\prime} G: S P: S^{\prime} P ;
\end{aligned}
$$

and therefore the angle between $S P$ and $S^{\prime} P$ produced is bisected by $P G$.

Hence $P T$ the tangent, which is perpendicular to $P G$, bisects the angle $S P S^{\prime \prime}$.

Cor. 1. If $P T$ and $G P$ produced meet, respectively, the conjugate axis in $t$ and $g$, it can be shewn, in exactly the same manner as in the corresponding case of the ellipse, Art. 64, that the circle which circumscribes $S P S^{\prime}$ also passes through $t$ and $g$.

Cor. 2. If an ellipse be described having $S$ and $S^{\prime \prime}$ for its foci, and if this ellipse meet the hyperbola in $P$, the normal at $P$ to the ellipse bisects the angle $S P S^{\prime \prime}$, and therefore coincides with the tangent to the hyperbola.

Hence, if an ellipse and an hyperbola be confocal, that is, have the same foci, they intersect at right angles.
105. Prop. IX. Every diameter is bisected at the centre, and the tangents at the ends of a diameter are parallel.

Let $P C p$ be a diameter, and $P N, p n$ the ordinates.

$$
\text { Then } \quad \begin{aligned}
C N^{2}: C n^{2} & :: P N^{2}: p n^{2}, \\
& :: C N^{2}-A C^{2}: C n^{2}-A C ;
\end{aligned}
$$

hence
and
$C N=C n$,
$\therefore C P=C p$.

Again, if $P T, p t$ be the tangents,
The triangles $P C S, p C S^{\prime}$ are equal in all respects, and therefore $S P S^{\prime} p$ is a parallelogram.

Hence the angles $S P S^{\prime}, S p S^{\prime \prime}$ are equal, and therefore $S P T=S^{\prime} p t$.

But $S P C=S^{\prime} p C$,
$\therefore$ the difference $T P C=$ the difference $t p C$, and $P T$ is parallel to $p t$.

It can be shewn in exactly the same manner, that, if the diameter be terminated by the conjugate hyperbola, it is bisected in $C$, and the tangents at its extremities are parallel.

Cor. The distances $S P, S p$ are equally inclined to the tangents at $\boldsymbol{P}$ and $p$.
106. Prop. X. The perpendiculars from the foci on any tangent meet the tangent on the auxiliary circle, and the semi-conjugate axis is a mean proportional between their lengths.

Let $S Y, S^{\prime} Y^{\prime}$ be the perpendiculars, and let $S Y$ produced meet $S^{\prime \prime} P$ in $L$.

Then the triangles $S P Y, L P Y$ are equal in all respects,

$$
\text { and } S Y=L Y
$$

Hence, $C$ being the middle point of $S S^{\prime}$ and $Y$ of $S L$, $C Y$ is parallel to $S^{\prime} L$, and $S^{\prime} L=2 C Y$.

But

$$
\begin{gathered}
S^{\prime} L=S^{\prime} P-P L=S^{\prime} P-S P=2 A C \\
\therefore C Y=A C
\end{gathered}
$$

and $Y$ is on the auxiliary circle.
So also $Y^{\prime}$ is a point in the circle.
Let $S Y$ produced meet the circle in $Z$, and join $Y^{\prime} Z$; then, $Y^{\prime} Y Z$ being a right angle, $Z Y^{\prime}$ is a diameter and passes through $C$. Hence, the triangles $S C Z, S^{\prime \prime} C Y^{\prime}$ being equal,

$$
S^{\prime \prime} Y^{\prime}=S Z,
$$

and $\quad S Y \cdot S^{\prime} Y^{\prime}=S Y \cdot S Z=S A \cdot S A^{\prime}=B C^{2}$.
Cor. 1. If $P^{\prime}$ be the other extremity of the diameter $P C$, the tangent at $P^{\prime}$ is parallel to $P Y$, and therefore $Z$ is the foot of the perpendicular from $S$ on the tangent at $P^{\prime}$.

Cor. 2. If the diameter $D C D^{\prime}$, drawn parallel to the tangent at $P$, meet $S^{\prime} P, S P$ in $E$ and $E^{\prime}, P E C Y$ is a parallelogram;

$$
\therefore P E=C Y=A C \text {, }
$$

and so also $\quad P E^{\prime}=C Y^{\prime}=A C$.
107. Prop. XI. To draw tangents to an hyperbola from a given point.

The construction of Art. (14) may be employed, or, as in the cases of the ellipse and parabola, the following.

Let $Q$ be the given point; join $S Q$, and upon $S Q$ as

diameter describe a circle intersecting the auxiliary circle in $Y$ and $Y^{\prime}$;
$Q Y$ and $Q Y^{\prime}$ are the required tangents.
Producing $S Y$ to $L$, so that $Y L=S Y$, draw $S^{\prime} L$ cutting $Q Y$ in $P$, and join $S P$.

The triangles $S P Y, L P Y$ are equal in all respects, and

$$
S^{\prime} P-S P=S^{\prime} L=2 C Y=2 A C
$$

$\therefore P$ is a point on the hyperbola.
Also $Q P$ bisects the angle $S P S^{\prime \prime}$, and is therefore the tangent at $P$. A similar construction will give the other tangent $Q P^{\prime}$.

If the point $Q$ be within the angle formed by the asymptotes, the tangents will both touch the same branch of the curve; but if it lie within the external angle, they will touch opposite branches.
108. Prop. XII. If two tangents be drawn from any point to an hyperbola they are equally inclined to the focal distances of that point.

Let $P Q, P^{\prime} Q$ be the tangents, $S Y, S^{\prime} Y^{\prime}, S Z, S^{\prime} Z^{\prime}$ the perpendiculars from the foci; join $Y Z, Y^{\prime} Z^{\prime}$.

Then the angles $Y S Z, Y^{\prime} S^{\prime} Z^{\prime}$ are equal, for they are the supplements of $Y Q Z, Y^{\prime} Q Z^{\prime}$.

Also

$$
\begin{gathered}
S Y \cdot S^{\prime \prime} Y^{\prime}=S Z \cdot S^{\prime} Z^{\prime}, \text { Art. (106); } \\
S Y: S Z:: S^{\prime} Z^{\prime}: S^{\prime} Y^{\prime} ;
\end{gathered}
$$

$\therefore$ the triangles $Y Z S, Y^{\prime} S^{\prime} Z^{\prime}$ are similar, and the angle $Y Z S=Z^{\prime} Y^{\prime} S^{\prime}$.
But the angle $Y Q S=Y Z S$, and $Z^{\prime} Q S^{\prime \prime}=Z Y^{\prime} S^{\prime}$;

$$
\therefore Y Q S=Z^{\prime} Q S^{\prime \prime} .
$$

That is, the tangent $Q P$, and the tangent $P^{\prime} Q$ produced, are equally inclined to $S Q$ and $S^{\prime} Q$.

Or, producing $S^{\prime \prime} Q, Q P$ and $Q P^{\prime}$ are equally inclined to $Q S$ and $S^{\prime} Q$ produced.

In exactly the same manner it can be shewn that if $Q P, Q P^{\prime}$ touch opposite branches of the curve the angles $P Q S, P^{\prime} Q S^{\prime}$ are equal.

Cor. If $Q$ be a point in a confocal hyperbola, the normal at $Q$ bisects the angle between $S Q$ and $S^{\prime \prime} Q$ produced and therefore bisects the angle $P Q P^{\prime}$.

Hence, if from any point of an hyperbola tangents be drawn to a confocal hyperbola, these tangents are equally
inclined to the normal or the tangent at the point, according as it lies within or without that angle formed by the asymptotes of the confocal which contains the transverse axes.
109. Prop. XIII. If $P T$, the tangent at $P$, meet the transverse axis in $T$, and $P N$ be the ordinate,

$$
C N . C T=A C^{2} .
$$

Let fall the perpendicular $S y$ upon $P T$, and join $y N$, $C y, S P$, and $S^{\prime} P$.

The angle $C y T=S^{\prime \prime} P y$

$$
\begin{aligned}
& =S P y \\
& =\text { the supplement of } S N y \\
& =C N y ;
\end{aligned}
$$

also the angle $y C T$ is common to the two triangles $C y T$, $C y N$; these triangles are therefore similar,
and
$C N: C y:: C y: C T$,
or
$C N . C T=C y^{2}=A C^{2}$.
Cor. 1. Hence $C N . N T=C N^{2}-C N . C T$

$$
\begin{aligned}
& =O N^{2}-A C^{2} \\
& =A N \cdot N A^{\prime} .
\end{aligned}
$$

Cor. 2. Hence also it follows that
If any number of hyperbolas be described having the same transverse axis, and an ordinate be drawn cutting
the hyperbolas, the tangents at the points of section will all meet the transverse axis in the same point.

Cor. 3. If $C N$ be increased indefinitely, $C T$ is diminished indefinitely, and the tangent ultimately passes through $C$, as we have already shewn, Art. (100).
110. Prop. XIV. If the tangent at $P$ meet the conjugate axis in $t$, and $P N$ be the ordinate,

$$
C t . P N=B C^{2} .
$$

For, Fig. Art. (109),
Then $\quad C t: P N:: C T: N T$;
$\therefore C t . P N: P N^{2}:: C T . C N: C N . N T$
:: $A C^{2}: A N . N A^{\prime}$.
$\therefore C t . P N: A C^{2}:: P N^{2}: A N . N A^{\prime}$,
:: $B C^{2}: A C^{2}$,
and

$$
C t . P N=B C^{2}
$$

111. Prop. XV. If the normal at $P$ meet the transverse axis in $G$, the conjugate axis in $g$, and the diameter parallel to the tangent at $P$ in $F$,

$$
P F . P G=B C^{2} \text {, and } P F . P g=A C^{2} .
$$

Let $N P, P M$, perpendicular to the axes, meet the dia-

meter $C F$ in $K$ and $L$, and let the tangent meet the axes in $T$ and $t$.

Then $K N G, K F G$ being right angles, a circle can be described about $K F N G$, and therefore

$$
\begin{aligned}
P F \cdot P G & =P K \cdot P N=C t \cdot P N \\
& =B C^{2} .
\end{aligned}
$$

Similarly a circle can be drawn through $F L M g$;

$$
\begin{aligned}
\therefore P F \cdot P g & =P L \cdot P M=C T \cdot C N, \\
& =A C^{2} .
\end{aligned}
$$

Cor. Hence $P G: P g:: B C^{2}: A C^{2}$.
Also $P N G, P M g$ are similar triangles;
or

$$
\therefore N G: M P:: P G: P g,
$$

r

$$
N G: C N: B C^{2}: A C^{2}
$$

Hence $C G: C N: S C^{2}: A C^{2}$.
As in the case of the ellipse, it can be shewn that

$$
C G . C T=C g . C t=S C^{2},
$$

and that $\quad C g: P N:: S C^{2}: B C^{2}$.
112. Prop. XVI. If $P C p$ be a diameter, and $Q V$ an ordinate, and if the tangent at $Q$ meet the diameter Pp in T,

$$
C V . C T=C P^{2}
$$

Let the tangents at $P$ and $p$ meet the tangent at $Q$ in $R$ and $r$;

Then the angle $S P R=S p r$, Cor. Art. (105), and therefore if $R N, r n$ be the perpendiculars on $S P, s p$, the triangles $R P N, r p n$ are similar.

Draw $R M, r m$ perpendiculars on $S Q$.
Then

$$
\begin{aligned}
T R: T r & :: R P: r p, \\
& :: R N: r n, \\
& :: R M: r m, \text { Cor. Art. (13), } \\
& :: R Q: r Q .
\end{aligned}
$$

Hence, $Q V, R P$, and $r p$ being parallel,

$$
\begin{gathered}
T P: T p:: P V: p V \\
\therefore T P+T p: T p-T P:: P V+p V: p V-P V,
\end{gathered}
$$

$$
\begin{gathered}
2 C P: 2 C T:: 2 C V: 2 C P, \\
C V . C T=C P^{2} .
\end{gathered}
$$

113. Prop. XVII. A diameter bisects all chords parallel to the tangents at its extremities.

Let $P C p$ be the diameter, and $Q Q^{\prime}$ the chord, parallel

to the tangents at $P$ and $p$. Then if the tangents $T Q$, $T Q^{\prime}$ at $Q$ and $Q^{\prime}$ meet the tangents at $P$ and $p$, in the points $E$. $E^{\prime}, e, e^{\prime}$,
$E P=E^{\prime} P$ and $e p=e^{\prime} p$, Art. (16);
$\therefore$ The point $T$ is on the line $P p$;
but $T P$ bisects $Q Q^{\prime}$;
that is, the diameter $p C P$ produced bisects $Q Q^{\prime}$.
Def. The line DCd, drawn parallel to the tangent at $P$, and terminated by the conjugate hyperbola, that is, the diamueter parallel to the tangent at $P$, is said to be conjugute to PCp.

A diameter therefore bisects all chords parallel to its conjugate.
114. Prop. XVIII. If the diameter $D C d$ be conjugate to $P C$, then will $P C p$ be conjugate to $D C d$.

Let the chord $Q V q$ be parallel to $C D$ and be bisected in $V$ by $C P$ produced.

Draw the diameter $q C R$, and join $R Q$ meeting $C D$ in $U$.

Then $R C=C q$ and $Q V=V q$;
$\therefore Q R$ is parallel to $C P$.

Also
and

$$
\begin{gathered}
Q U: U R:: C q: C R, \\
\quad \therefore Q U=U R
\end{gathered}
$$

that is, $C D$ bisects the chords parallel to $C P$, and $P C p$ is therefore conjugate to $D C d$.

Hence when two diameters are conjugate, each bisects the chords parallel to the other.

Def. Chords drawn from the extremities of any diameter to a point on the hyperbola are called supplemental chords.

Thus, $q Q, Q R$ are supplemental chords, and they are parallel to $C D$ and $C P$; supplemental chords are therefore parallel to conjugate diameters.

Def. A line $Q V$, drawn from any point $Q$ of an hyperbola, parallel to a diameter DCd, and terminated by the conjugate diameter PCp, is called an ordinate of the diameter PCp, and if QV produced meet the curve in $Q^{\prime}, Q V Q^{\prime}$ is the double ordinate.

This definition includes the two cases in which $Q Q^{\prime}$ may be drawn so as to meet the same, or opposite branches of the hyperbola.
115. Prop. XIX. Any diameter is a mean proportional between the transverse axis and the focal chord parallel to the diameter.

This can be proved as in Art. 76.

## Properties of Asymptotes.

116. Prop. XX. If from any point $Q$ in an asymptote QPpq be drawn meeting the curve in $P, p$ and the other asymptote in $q$, and if $C D$ be the semi-diameter parallel to $Q q$,

$$
Q P . P q=C D^{2} \text { and } Q P=p q .
$$

Through $P$ and $D$ draw $R P r, D T t$ perpendicular to the transverse axis, and meeting the asymptotes.

Then

$$
Q P: R P:: C D: D T,
$$

$$
\text { and } \quad P q: P r:: C D: D t ;
$$

$\therefore Q P . P q: R P . P r:: C D^{2}: D T . D t$.
But

$$
\begin{gathered}
R P . P r=B C^{2}=D T \cdot D t, \text { Art. (103), } \\
\therefore Q P \cdot P q=C D^{2} .
\end{gathered}
$$

Similarly

$$
q p \cdot p Q=C D^{2} ;
$$

$$
\therefore Q P \cdot P q=q p \cdot p Q
$$

or, if $V$ be the middle point of $Q q$,

$$
Q V^{2}-P V^{2}=Q V^{2}-p V^{2}
$$

Hence

$$
P V=p V
$$

$$
\text { and } \therefore P Q=p q \text {. }
$$

We have taken the case in which $Q q$ meets one branch of the hyperbola. It may however be shewn in the same manner that the same relations hold good for the case in which $Q q$ meets opposite branches.
B. C. S.

Cor. If a straight line $P P^{\prime} p^{\prime} p$ meet the hyperbola in $P, p$, and the conjugate hyperbola in $P^{\prime}, p^{\prime}, P P^{\prime}=p p^{\prime}$.

For, if the line meet the asymptotes in $Q, q$,
and

$$
\begin{aligned}
Q P^{\prime} & =p^{\prime} q, \\
P Q & =q p ; \\
\therefore P P^{\prime} & =p p^{\prime} .
\end{aligned}
$$

117. Prop. XXI. The portion of a tangent, which is terminated by the asymptotes, is bisected at the point of contact, and is equal to the parallel diameter.
$L E l$ being the tangent, Fig. Art. (116), and DCd the parallel diameter, draw any parallel straight line $Q P p q$ meeting the curve and the asymptotes.

Then $Q P=p q$; and, if the line move parallel to itself until it coincides with $L l$, the points $P$ and $p$ coincide with $E$, and $\therefore L E=E l$.

Also $\quad \begin{aligned} Q P . P q & =C D^{2}, \text { always, and therefore } \\ L E \cdot E L & =C D^{2}, \\ \text { or } L E & =C D .\end{aligned}$
It may be noticed that since the asymptotes are tangents, the fact that $L E=E l$ is a particular case of the general property demonstrated in Art. (16).

## Properties of Conjugate Diameters.

118. Prop. XXII. Conjugate diameters of an hyperbola are also conjugate diameters of the conjugate hyperbola, and the asymptotes are diagonals of the parallelogram formed by the tangents at their extremities.
$P C p$ and $D C d$ being conjugate, let $Q V q$, a double ordinate of $C D$, meet the conjugate hyperbola in $Q^{\prime}$ and $q^{\prime}$.
Then
$Q V=V q$,
and

$$
Q Q^{\prime}=q q^{\prime}, \text { Cor. Art. (116); }
$$

$$
\therefore Q^{\prime} V=V q^{\prime}
$$

That is, $C D$ bisects the choras of the conjugate hyperbola parallel to $C P$.

Hence $C D$ and $C P$ are conjugate in both hyperbolas, and therefore the tangent at $D$ is parallel to $C P$.

Let the tangent at $P$ meet the asymptote in $L$; then

$$
P L=C D . \quad \text { Art. (117). }
$$

Hence $L D$ is parallel and equal to $C P$; lut the tangent at $D$ is parallel to $C P$;
$\therefore L D$ is the tangent at $D$.
Completing the figure, the tangents at $p$ and $d$ are parallel to those at $P$ and $D$, and therefore the asymptotes are the diagonals of the parallelogram $L l l^{\prime} L^{\prime}$.

Cor. Hence, joining $P D$, it follows that $P D$ is parallel to the asymptote $l C L^{\prime}$, since $L P=P L^{\prime}$, and $L D=D l$.
119. Prop. XXIII. If $Q V$ be an ordinate of a diameter PCp, and DCd the conjugate diameter,

$$
Q V^{2}: P V . V p:: C D^{2}: C P^{2} .
$$

Let $Q V$, and the tangent at $P$, meet the asymptote in $R$ and $L$.

Then $L P$ being equal to $C D$,

$$
R V^{2}: C D^{2}:: C V^{2}:: C P^{2} ;
$$

$$
\therefore R V^{2}-C D^{2}: C D^{2}:: C V^{2}-C P^{2}: C P^{2}
$$

But

$$
R V^{2}-Q V^{2}=C D^{2} .
$$

Hence $Q V^{2}: C D^{2}:: C V^{2}-C P^{2}: C P^{2}$,

$$
\text { or } Q V^{2}: P V . V p:: C D^{2}: C P^{2} .
$$

120. Prop. XXIV. If $Q V$ be an ordinate of a dameter $P C P$, and if the tangent at $Q$ meet the conjugate diameter, $D C d$, in $t$,

$$
C t . Q V=C D^{2}
$$

For, fig. Art. (113),

$$
\begin{gathered}
C t: Q V:: C T: V T, \\
\text { and } \therefore C t . Q V: Q V^{2}:: C V . C T: C V \cdot V T . \\
\text { But } \quad C V . C T=C P^{2}, \quad \text { Art. (112), } \\
\text { and } C V . V T=C V^{2}-C V . C T=C V^{2}-C P^{2} ; \\
\therefore C t \cdot Q V: Q V^{2}:: C P^{2}: C V^{2}-C P^{2} \\
:: C D^{2}: Q V^{2} . \text { Art. (119). }
\end{gathered}
$$

Hence

$$
C t . Q V=C D^{2}
$$

121. Prop. XXV. If $A C a, B C b$ be conjugate tiameters, and PCp, DC another pair of conjugate didmeters, and if PN, DM be ordinates of $A C a$,

$$
C M: P N:: A C: B C,
$$

$$
\text { and } D M: C N:: B C: A C .
$$

Let the tangents at $P$ and $D$ meet $A C a$ in $T$ and $t$;

then $C N . C T=A C^{3}=C M . C t$, Arts. (112) and (120),

$$
\begin{aligned}
\therefore C M: C N & :: C T: C t, \\
& :: P T: C D, \\
& :: P N: D M, \\
& :: C N: M t ;
\end{aligned}
$$

$$
\therefore C N^{2}=C M . M t=C M^{2}+C M . C t
$$

$$
=C M^{2}+A C^{2}
$$

and $\quad C M^{2}=C N^{2}-A C^{2}$.
But

$$
\begin{aligned}
& P N^{2}: C N^{2}-A C^{2}:: B C^{2}: A C^{2} \\
& \therefore P N: C M: B C: A C
\end{aligned}
$$

and, similarly, $\quad D M: C N$ :: $B C: A C$.
Cor. We have shewn in the course of the proof, that

$$
C N^{2}-C M^{2}=A C^{2} .
$$

Similarly, if $P n, D m$ be ordinates of $B C$,

$$
C m^{2}-C n^{2}=B C^{2} ;
$$

that is,

$$
D M^{2}-P N^{2}=B C^{2} ;
$$

and it must be noticed that these relations are shewn for any pair of conjugate diameters $A C a, B C b$, including of course the axes.
122. Prop. XXVI. If $C P, C D$ be conjugate semidiameters, and $A C, B C$ the semi-axes,

$$
C P^{2}-C D^{2}=A C^{2}-B C^{2}
$$

For, drawing the ordinates $P N, D M$, and remembering that in this case the angles at $N$ and $M$ are right angles, we have, from the figure of the previous article,

$$
\begin{aligned}
& C P^{2}=C N^{2}+P N^{2} \\
& C D^{2}=C M^{2}+D M^{2}
\end{aligned}
$$

But $C N^{2}-C M^{2}=A C^{2}$ and $D M^{2}-P N^{2}=B C^{2}$;

$$
\therefore C P^{z}-C D^{y}=A C^{2}-B C^{2}
$$

123. Prop. XXVII. If the normal at $P$ meet the axes in $G$ and $g$,
and

$$
\begin{gathered}
P G: C D:: B C: A C, \\
P g: C D:: A C: B C .
\end{gathered}
$$

For the proofs of these relations, see Art. (79).
Observe also that

$$
P G \cdot P g=C D^{2},
$$

and that

$$
G g: C D:: S C^{2}: A C . B C .
$$

124. Prop. XXVIII. The area of the parallelogram formed by the tangents at the ends of conjugate diameters is equal to the rectangle contained by the axes.

Let $C P, C D$ be the semi-diameters, and $P N, D M$ the ordinates of the transverse axis.

Let the normal at $P$ meet $C D$ in $F$, and the axis in $G$. Then $P N G, C D M$ are similar triangles, and, exactly as in Art. (80), it can be shewn that

$$
P F . C D=A C . B C .
$$

125. Prop. XXIX. If $S P, S^{\prime} P$ be the focal distance of a point $P$, and $C D$ be conjugate to $C P$,

$$
S P \cdot S^{\prime \prime} P=C D^{2}
$$

Attending to the figure of Art. (106), the proof is the same as that of Art. (81).
126. Prop XXX. If the tangent at $P$ meet a pair of conjugate diameters in $T$ and $t$, and $C D$ be conjugate to $C P$,

$$
P T . P t=C D^{2} .
$$

This can be proved as in Art. (82).
It can also be shewn that if the tangent at $P$ meet two parallel tangents in $T^{\prime}$ and $t^{\prime}$,

$$
P T^{\prime \prime} . P t^{\prime}=C D^{2} .
$$

127. Prop. XXXI. If the tangent at $P$ meet the asymptotes in $L$ and $L^{\prime}$,

$$
C L . C L^{\prime}=S C^{2}
$$

Let the tangent at $A$ meet the asymptotes in $K$ and

$K^{\prime}$; then, Arts. 118 and 124, the triangles $L C L^{\prime}, K C K^{\prime}$ are of equal area, and therefore

$$
C L: C K^{\prime}:: C K: C L^{\prime}, \text { Euclid, Book vi., }
$$

or

$$
\begin{aligned}
C L \cdot C L^{\prime} & =C K^{2} \\
& =A C^{2}+B C^{2}=S C^{2} .
\end{aligned}
$$

Cor. If $P H, P H^{\prime}$ be drawn parallel to, and terminated by the asymptotes,

$$
\text { 4. } P H \cdot P H^{\prime}=C S^{2},
$$

for $C L=2 P H^{\prime}$, and $C L^{\prime}=2 P H$.
128. Prop. XXXII. Pairs of tangents at right angles to each other intersect on a fixed circle.
$P T, Q T$ being two tangents at right angles, let $S Y$, perpendicular to $P T$, meet $S^{\prime} P$ in $K$.

Then, Art. (108), the angle

$$
S^{\prime} T Y^{\prime}=Q T S,
$$

and obviously, $K T P=P T S ;$
therefore $S^{\prime} T Y^{\prime}$ is complementary to $K T P$, and $S^{\prime} T K$ is a right angle.

Hence

$$
\begin{aligned}
4 A C^{2} & =S^{\prime} K^{2}=S^{\prime} T^{2}+T K^{2} \\
& =S^{\prime} T^{2}+S T^{2} \\
& =2 . C T^{12}+2 . C S^{2} \text { by Euclid II. } 12 \text { and } 13 ;
\end{aligned}
$$

$$
\therefore C T^{2}=A C^{2}-B C^{2},
$$

and the iocus of $T$ is a circle.
If $A C$ be less than $B C$, this relation is impossible.
In this case, however, the angle between the asymptotes is greater than a right angle, and the angle $P T Q$ between a pair of tangents being always greater than the angle between the asymptotes is greater than a right angle. The problem is therefore à priori impossible for the hyperbola, but becomes possible for the conjugate hyperbola.

As in the case of the ellipse, the locus of $T$ is called the director circle.
129. Prop. XXXIII. The rectangles contained by the segments of any two chords which intersect each other are in the ratio of the squares on the parallel diameters.

Through any point $O$ in a chord $Q O Q^{\prime}$ draw the dia-

meter $O R R^{\prime}$; and let $C D$ be parallel to $Q Q^{\prime}, C P$ conjugate to $C D$, and bisecting $Q Q^{\prime}$ in $V$.

Draw $R U$ an ordinate of $C P$.
Then

$$
\begin{aligned}
R U^{2}: C U^{2}-C P^{2} & :: C D^{2}: C P^{2}, \\
\therefore C D^{2}+R U^{2}: C U^{2} & : C D^{2}: C P^{2}, \\
& :: C D^{2}+Q V^{2}: C V^{2} .
\end{aligned}
$$

But $\quad R U^{2}: C U^{2}: O V^{2}: C V^{2}$;

$$
\therefore C D^{2}: C U^{2}:: C D^{2}+Q V^{2}-O V^{2}: C V^{2},
$$

or

$$
C D^{2}: C D^{2}+Q V^{2}-O V^{2}: C U^{2}: C V^{2}
$$

$$
:: C R^{2}: C O^{2}
$$

$\therefore C D^{2}: Q V^{2}-O V^{2}: C R^{2}: C O^{2}-C R^{2}$,
or $C D^{2}: Q O . O Q^{\prime}: C R^{2}: O R . O R^{\prime}$.

Similarly, if $q O q^{\prime}$ be any other chord, and $C d$ the parallel semi-diameter,

$$
\begin{aligned}
& C d^{2}: q O . O q^{\prime}:: C R^{2}: O R . O R^{\prime} \\
& \therefore Q O . O Q^{\prime}: q O . O q^{\prime}:: C D^{2}: C d^{2}
\end{aligned}
$$

that is, the ratio of the rectangles depends only on the directions of the chords.

Prop. XXXIV. If a circle intersect an hyperbola in four points, the several pairs of the chords of intersection are equally inclined to the axes.

For the proof, see Art. (87).

## Examples.

1. If a circle be drawn so as to touch two fixed circles externally, the locus of its centre is an hyperbola.
2. If the tangent at $B$ to the conjugate meet the latus rectum in $D$, the triangles $S C D, S X D$ are similar.
3. The straight line drawn from the focus to the directrix, parallel to an asymptote, is equal to the semi-latus-rectum, and is bisected by the curve.
4. Given the asymptotes and a focus, find the directrix.
5. Given the centre, one asymptote, and a directrix, find the focus.
6. Parabolas are described passing through two fixed points, and having their axes parallel to a fixed line; the locus of their foci is an hyperbola.
7. The base of a triangle being given, and also the point of contact with the base of the inscribed circle, the locus of the vertex is an hyperbola.
8. If the normal at $P$ meet the conjugate axis in $g$, and $g N$ be the perpendicular on $S P$, then $P N=A C$.
9. Draw a tangent to an hyperbola, or its conjugate, parallel to a given line.
10. If $A A^{\prime}$ be the axis of an ellipse, and $P N P^{\prime}$ a double ordinate, the locus of the intersection of $A^{\prime} P$ and $P^{\prime} A$ is an hyperbola.
11. The tangent at $P$ bisects any straight line perpendicular to $A A^{\prime}$, and terminated by $A P$, and $A^{\prime} P$.
12. If $P C p$ be a diameter, and if $S p$ meet the tangent at $P$ in $T$,

$$
S P=S T .
$$

13. Given an asymrtote, the focus, and a point; construct the hyperbola.
14. A circle can be drawn through the foci and the intersections of any tangent with the tangents at the vertices.
15. Given an asymptote, the directrix, and a point; construct the hyperbola.
16. If through any point of an hyperbola straight lines are drawn parallel to the asymptotes and meeting any semi-diameter $C Q$ in $P$ and $R$,

$$
C P . C R=C Q^{2} .
$$

17. $P N$ is an ordinate and $N Q$ parallel tn $A B$ meets the conjugate axis in $Q$; prove that $Q B . Q B^{\prime}=P N^{2}$.
18. $N P$ is an ordinate and $Q$ a point in the curve; $A Q$, $A^{\prime} Q$ meet $N P$ in $D$ and $E$; prove that $N D . N E=N P^{2}$.
19. If a tangent cut the major axis in the point $T$, and perpendiculars $S Y, H Z$ be let fall on it from the foci, then

$$
A T \cdot A^{\prime} T=Y T . Z T
$$

20. In the tangent at $P$ a point $Q$ is taken such that $P Q$ is proportional to $C D$; shew that the locus of $Q$ is an hyperbola.
21. Tangents are drawn to an hyperbola, and the portion of each tangent intercepted by the asymptotes is divided in a constant ratio; prove that the locus of the point of section is an hyperbola.
22. If the tangent and normal at $P$ meet the conjugate axis in $t$ and $K$ respectively, prove that a circle can be drawn through the foci and the three points $P, t, K$.

Shew also that

$$
\begin{array}{r}
G K: S K \\
S t: t K
\end{array}: S A: A X, B C, C D,
$$

and
$C D$ being conjugate to $C P$.
23. Shew that the points of trisection of a series of conterminous circular arcs lie on branches of two hyperbolas; and determine the distance between their centres.
24. If the tangent at any point $P$ cut an asymptote in $T$, and if $S P$ cut the same asymptote in $Q$, then $S Q=Q T$.
25. A series of hyperbolas having the same asymptotes is cut by a straight line parallel to one of the asymptotes, and through the points of intersection lines are drawn parallel to the other, and equal to either semi-axis of the corresponding hyperbola: prove that the locus of their extremities is a parabola.
26. Prove that the rectangle $P Y . P Y^{\prime}$ in an ellipse is equal to the square on the conjugate axis of the confocal hyperbola passing through $P$.
27. If the tangent at $P$ meet one asymptote in $T$, and a line $T Q$ be drawn parallel to the other asymptote to meet the curve in $Q$; prove that if $P Q$ be joined and produced both ways to meet the asymptotes in $R$ and $R^{\prime}, R R^{\prime}$ will be trisected at the points $P$ and $Q$.
28. The tangent at a point $P$ of an ellipse meets the hyperbola having the same axes as the ellipse in $C$ and $D$. If $Q$ be the middle point of $C D$, prove that $O Q$ and $O P$ are equally inclined to the axes, $O$ being the centre of the ellipse.
29. Given one asymptote, the direction of the other, and the position of one focus, determine the position of the vertices.
30. Two points are taken on the same branch of the curve, and on the same side of the axis; prove that a circle can be drawn touching the four focal distances.
31. Supposing the two asymptotes and one point of the curve to be given in position, shew how to construct the curve; and find the position of the foci.
32. Given a pair of conjugate diameters, construct the axes.
33. If $P H, P K$ be drawn parallel to the asymptotes from a point $P$ on the curve, and if a line through the centre meet them in $R, T$, and the parallelogram $P R Q T$ be completed, $Q$ is a point on the curve.
34. The ordinate $N P$ at any point of an ellipse is produced to a point $Q$, such that $N Q$ is equal to the subtangent at $P$; prove that the locus of $Q$ is an hyperbola.
35. If a given point be the focus of any hyperbola, passing through a given point and touching a given straight line, prove that the locus of the other focus is an are of a fixed hyperbola.
36. An ellipse and hyperbola are described, so that the foci of each are at the extremities of the transverse axis of the other; prove that the tangents at their points of intersection meet the conjugate axis in points equidistant from the centre.
37. A circle is described about the focus as centre, with a radius equal to one-fourth of the latus rectum: prove that the focal distances of the points at which it intersects the hyperbola are parallel to the asymptotes.
38. The tangent at any point forms a triangle with the asymptotes: determine the locus of the point of intersection of the straight lines drawn from the angles of this triangle to bisect the opposite sides.
39. If $S Y, S^{\prime} Y^{\prime}$ be the perpendiculars on the tangent at $P$, a circle can be drawn through the points $Y, Y^{\prime}, N, C$.
40. The straight lines joining each focus to the foot of the perpendicular from the other focus on the tangent meet on the normal and bisect it.
41. If the tangent and normal at $P$ meet the axis in $T$ and $G, N G . C T=B C^{2}$.
42. If the tangent at $P$ meet the axes in $T$ and $t$, the angles $P S t, S T P$ are supplementary.
43. If the tangent at $P$ meet any conjugate diameters in $T$ and $t$, the triangles $S P T, S^{\prime} P t$ are similar.
44. If the diameter conjugate to $C P$ meet $S P$ and $S^{\prime} P$ in $E$ and $E^{\prime}$, prove that the circles about the triangles $S C E, S^{\prime} C E^{\prime \prime}$ are equal.
45. The locus of the centre of the circle inscribed in the triangle $S P S^{\prime}$ is a straight line.
46. If $P N$ be an ordinate, and $N Q$ parallel to $A P$ meet $C P$ in $Q, A Q$ is parallel to the tangent at $P$.
47. If an asymptote meet the directrix in $D$, and the tangent at the vertex in $E, A D$ is parallel to $S E$.
48. The radius of the circle touching the curve and its asymptotes is equal to the portion of the latus rectum produced, between its extremity and the asymptote.
49. If $G$ be the foot of the normal, and if the tangent meet the asymptotes in $L$ and $M, G L=G M$.
50. With two conjugate diameters of an ellipse as asymptotes, a pair of conjugate hyperbolas is constructed: prove that if one hyperbola touch the ellipse, the other will do so likewise; prove also that the diameters drawn through the points of contact are conjugate to each other.
51. If two tangents be drawn the lines joining their intersections with the asymptotes will be parallel.
52. The locus of the centre of the circle touching $S P, S^{\prime} P$ produced, and the major axis, is an hyperbola.
53. If from a point $P$ in an hyperbola, $P K$ be drawn parallel to an asymptote to meet the directrix in $K$, then $P K=S P$.
54. If $P D$ be drawn parallel to an asymptote, to meet the conjugate hyperbola in $D, C P$ and $C D$ are conjugate diameters.
55. If $Q R$ be a chord parallel to the tangent at $P$, and if $Q L, P N, R M$ be drawn parallel to one asymptote to meet the other,

$$
C L . C M=C N^{2} .
$$

56. If a circle touch the transverse axis at a focus, and pass through one end of the conjugate, the chord intercepted by the conjugate is a third proportional to the conjugate and transverse semi-axes.
57. A line through one of the vertices; terminated by two lines drawn through the other vertex parallel to the asymptotes, is bisected at the other point where it cuts the curve.
58. If $P S Q$ be a focal chord, and if the tangents at $P$ and $Q$ meet in $T$, the difference between $P T Q$ and half $P S^{\prime} Q$ is a right angle.
59. If a straight line passing through a fixed point $C$ meet two fixed lines $O A, O B$ in $A$ and $B$, and if $P$ be taken in $A B$ such that $C P^{2}=C A . C B$, the locus of $P$ is an hyperbola, having its asymptotes parallel to $O A, O B$.
60. If from the points $P$ and $Q$ in an hyperbola there be drawn $P L, Q M$ parallel to each other to meet one asymptote, and $P R, Q N$ also parallel to each other to meet the other asymptote, $P L . P R=Q M . Q N$.
61. Prove that the locus of the point of intersection of two tangents to a parabola which cut at a constant angle is an hyperbola, and that the angle between its asymptotes is double the external angle between the tangents.
62. An ordinate $V Q$ of any diameter $C P$ is produced to meet the asymptote in $R$, and the conjugate hyperbola in $Q^{\prime}$; prove that $\quad Q V^{2}+Q^{\prime} V^{2}=2 R V^{2}$.

Prove also that the tangents at $Q$ and $Q^{\prime}$ meet the diameter $C P$ in points equidistant from $C$.
63. A chord QPL meets an asymptote in $L$, and a tangent from $L$ is drawn touching at $R$; if $P M, R E, Q N$, be drawn parallel to the asymptote to meet the other,

$$
P M+Q N=2 . R E .
$$

64. Tangents are drawn from any point in a circle through the foci; prove that the lines bisecting the angle between the tangents, or between one tangent and the other produced, all pass through a fixed point.
65. If a circle through the foci meet two confocal hyperbolas in $P$ and $Q$, the angle between the tangents at $P$ and $Q$ is equal to $P S Q$.
66. If $S Y, S^{\prime} Y^{\prime}$ be perpendiculars on the tangent at $P$, and if $P N$ be the ordinate, the angles $P N Y, P N Y^{\prime}$ are supplementary.
67. Find the position of $P$ when the area of the triangle $Y C Y^{\prime}$ is the greatest possible, and shew that, in that case,

$$
P N . S C=B C^{2} .
$$

68. If the tangent at $P$ meet the conjugate axis in $t$, the areas of the triangles $S P S^{\prime}, S t S^{\prime}$ are in the ratio of $C D^{2}: S t^{2}$.
69. If $S Y, S Z$ be perpendiculars on two tangents which meet in $T, Y Z$ is perpendicular to $S^{\prime} T$.
70. A circle passing through a focus, and having its centre on the transverse axis, touches the curve; shew that the focal distance of the point of contact is equal to the Latus Rectum.
71. If $C Q$ be conjugate to the normal at $P$, then is $C P$ conjugate to the normal at $Q$.
72. From a point in the auxiliary circle lines are drawn touching the curve in $P$ and $P^{\prime}$; prove that $S P, S^{\prime} P^{\prime}$ are parallel.
73. If the tangent and normal at $P$ meet the axis in $T$ and $G$,

$$
C T . C G=S C^{2} .
$$

74. Find the locus of the points of contact of tangents to a series of confocal hyperbolas from a fixed point in the axis.
75. Tangents to an hyperbola are drawn from any point in one of the branches of the coujugate, shew that the chord of contact will touch the other branch of the conjugate.
76. An ordinate $N P$ meets the conjugate hyperbola in $Q$; prove that the normals at $P$ and $Q$ meet on the transverse axis.
77. A parabola and an hyperbola have a common focus $S$ and their axes in the same direction. If a line $S P Q$ cut the curves in $P$ and $Q$, the angle between the tangents at $P$ and $Q$ is equal to half the angle between the axis and the other focal distance of the hyperbola.
78. If a hyperbola be described touching the four sides of a quadrilateral which is inscribed in a circle, and one focus lie on the circle, the other focus will also lie on the circle.
79. A conic section is drawn touching the asymptotes of an hyperbola. Prove that two of the chords of intersection of the curves are parallel to the chord of contact of the conic with the asymptotes.
80. A parabola $P$ and an hyperbola $H$ have a common focus, and the asymptotes of $H$ are tangents to $P$; prove that the tangent at the vertex of $P$ is a directrix of $H$, and that the tangent to $P$ at the point of intersection passes through the further vertex of $H$.
81. From a given point in an hyperbola draw a straight line such that the segment intercepted between the other intersection with the hyperbola and a given asymptote shall be equal to a given line.

When does the problem become impossible?
82. If an ellipse and a confocal hyperbola intersect in $P$, an asymptote passes through the point on the auxiliary circle of the ellipse corresponding to $P$.
83. $P$ is a point on an hyperbola whose foci are $S$ and $H$; another hyperbola is described whose foci are $S$ and $P$, and whose transverse axis is equal to $S P-2 P H$ : shew that the hyperbolas will meet only at one point, and that they will have the same tangent at that point.
84. A point $D$ is taken on the axis of an hyperbola, of which the excentricity is 2 , such that its distance from the focus $S$ is equal to the distance of $S$ from the further vertex $A^{\prime} ; P$ being any point on the curve, $A^{\prime} P$ meets the latus rectum in $K$. Prove that $D K$ and $S P$ intersect on a certain fixed circle.
85. Shew that the locus of the point of intersection of tangents to a parabola making with each other a constant angle equal to half a right angle, is an hyperbola.
86. The tangent and normal at any point intersect the asymptotes and axes respectively in four points which lie on a circle passing through the centre of the curve.

The radius of this circle varies inversely as the perpendicular from the centre on the tangent.
87. The difference between the sum of the squares of the distances of any point from the ends of any diameter and the sum of the squares of its distances from the ends of the conjugate is constant.
83. If a tangent meet the asymptotes in $L$ and $M$, the angle subtended by $L M$ at the farther focus is half the angle between the asymptotes.
89. If $P N$ be the ordinate of $P$, and $P T$ the tangent, prove that $S P$ : $S T$ :: $A N: A T$.
90. If an ellipse and an hyperbola are confocal, the asymptotes pass through the points on the auxiliary circle of the ellipse which correspond to the points of intersection of the two curves.
91. Two adjacent sides of a quadrilateral are given in magnitude and position; if the quadrilateral be such that a circle can be inscribed in it, the locus of the point of intersection of the other two sides is an hyperbola.
92. The tangent at $P$ meets the conjugate axis in $t$, and $t Q$ is perpendicular to $S P$; prove that $S Q$ is of constant length.
93. An hyperbola, having a given transverse axis, has one focus fixed, and always touches a given straight line; the locus of the other focus is a circle.
94. A chord $P R V Q$ meets the directrices in $R$ and $V$; shew that $P R$ and $V Q$ subtend, each at the focus nearer to $i t$, angles of which the sum is equal to the angle between the tangents at $P$ and $Q$.
95. A circle is drawn touching the transverse axis of an hyperbola at its centre, and also touching the curve; prove that the diameter conjugate to the diameter through either point of contact is equal to the distance between the foci.
96. A parabola is described touching the conjugate axes of an hyperbola at their extremities; prove that one asymptote is parallel to the axis of the parabola, and that the other asymptote is parallel to the chords of the parabola bisected by the first.

If a straight line parallel to the second asymptote meet the hyperbola and its conjugate in $P, P^{\prime}$, and the parabola in $Q, Q^{\prime}$, it may be shewn that $P Q=P^{\prime} Q^{\prime}$.
97. If two points $E$ and $E^{\prime}$ be taken in the normal $P G$ such that $P E=P E^{\prime}=C D$, the loci of $E$ and $E^{\prime}$ are hyperbolas having their axes equal to the sum and difference of the axes of the given hyperbola.
98. The angular point $A$ of a triangle $A B C$ is fixed, and the angle $\boldsymbol{A}$ is given, while the points $B$ and $C$ move on a fixed straight line; prove that the locus of the centre of the circle circumscribing the triangle is an hyperbola, and that the envelope of the circle is another circle.
99. If a conic be described having for its axes the tangent and normal at any point of a given ellipse, and touching at its centre the axis-major of the given ellipse, and if another conic be described in the same manner but touching the minor axis at the centre, prove that the foci of these conics lie in two circles concentric with the given ellipse, and having their diameters equal to the sum and difference of its axes.
100. An ellipse and an hyperbola are confocal; if a tangent to one intersect at right angles a tangent to the other, the locus of the point of intersection is a circle.

Shew also that the difference of the squares on the distances from the centre of parallel tangents is constant.
101. If a circle passing through any point $P$ of the curve, and having its centre on the normal at $P$, meets the curve again in $Q$ and $R$, the tangents at $Q$ and $R$ intersect on a fixed straight line.
102. If the tangent at $P$ meet an asymptote in $T$, the angle between that asymptote and $S^{\prime} P$ is double the angle $S T P$.
103. Four tangents to an hyperbola form a rectangle. If one side $A B$ of the rectangle intersect a directrix in $F$, and $S$ be the corresponding focus, the triangles $F S A, F B S$ are similar.
104. An ellipse and hyperbola have the same transverse axis, and their eccentricities are the reciprocals of one another; prove that the tangents to each through the focus of the other intersect at right angles in two points and also meet the conjugate axis on the auxiliary circle.
105. The tangent and normal at any point of an hyperbola intersect the asymptotes and axes respectively in four points which lie on a circle passing through the centre of the hyperbola, and the radius of this circle varies inversely as the distance of the tangent from the centre.

## CHAPTER V.

## THE RECTANGULAR HYPERBOLA.

If the axes of an hyperbola be equal, the angle between the asymptotes is a right angle, and the curve is called equilateral or rectangular.
130. Prop. 1. In a rectangular hyperbola

$$
C S^{2}=2 A C^{2}, \text { and } S A^{2}=2 A X^{2} .
$$

For

$$
C S^{2}=A C^{2}+B C^{2}=2 A C^{2},
$$

and

$$
\begin{gathered}
S A: A X:: S C: A C ; \\
\therefore S A^{2}=2 A X^{2} .
\end{gathered}
$$

Observe that in the figure of Art. (9S), $S D C$ is an isosceles triangle, since

$$
S D=B C, \text { and } C D=A C,
$$

and therefore

$$
S D=D C .
$$

131. Prop. II. The asymptotes of a rectangular hyperbola bisect the angles between any pair of conjugate diameters.

For, in a rectangular or equilateral hyperbola,

$$
C A=C B,
$$

and therefore, since $C P^{2}-C D^{2}=C A^{2}-C B^{2}$,

$$
C P=C D,
$$

$C P, C D$ being any conjugate semi-diameters.

The Rectangular Hyperbola.
Also, figure Art. (118), the parallelogram CPLD is a rhombus, and therefore $C L$ bisects the angle $P C D$.

Cor. Supplemental chords are equally inclined to the asymptotes, for they are parallel to conjugate diameters.
132. Prop. III. If $C Y$ be the perpendicular from the centre on the tangent at $P$, the angle $P C Y$ is bisected by the transverse axis, and half the transverse axis is a mean proportional between $C Y$ and $C P$.

For the angle
and

$$
\begin{aligned}
P C L & =D C L \\
& =Y C L^{\prime}, \\
\therefore P C A & =A C Y .
\end{aligned}
$$

Hence it follows that the triangles $P C N, T C Y$ are similar, and that

$$
\begin{gathered}
C Y: C T:: C N: C P \\
\therefore C Y \cdot C P=C T \cdot C N=A C^{2}
\end{gathered}
$$

134 The Rectangular Hyperbo'a.
133. Prop. IV. Diameters at right angles to tach other are equal.

Let $C P, C P^{\prime}$ be semi-diameters at right angles to each other, and $C D$ conjugate to $C P$.

Then, if $C L, C L^{\prime}$ be the asymptotes, the angle

$$
\begin{aligned}
P^{\prime} C L^{\prime} & =P C L \\
& =D C L ; \\
\therefore C P^{\prime} & =C D=C P .
\end{aligned}
$$

134. Prop. V. If the normal at $P$ meet the axes in $G$ and $g$,

$$
C N=N G \text { and } P G=P g=C D,
$$

$C D$ being conjugate to $C P$.
For, Art. (111),

$$
\begin{gathered}
N G: C N:: B C^{2}: A C^{2} ; \\
\therefore N G=C N .
\end{gathered}
$$

Also

$$
\begin{aligned}
& P F \cdot P G= B C^{2} \text { and } P F \cdot P g=A C^{2} ; \\
& \therefore P G=P g .
\end{aligned}
$$

Further, Art. (123),

$$
\begin{gathered}
P G: C D:: B C: A C ; \\
\quad \therefore P G=C D .
\end{gathered}
$$

135. Prop. VI. If $Q V^{-}$be an ordinate of a diameier $P C P$,

$$
Q V^{2}=P V \cdot V_{p}
$$

For $\quad Q V^{2}: P V . V p: C D^{2}: C P^{2}$,
and

$$
\begin{gathered}
C D=C P ; \\
Q V^{2}=P V \cdot V p=C V^{2}-C P^{2} .
\end{gathered}
$$

136. Prop. VII. The angle between a chord $P Q$, and the tangent at $P$, is equal to the angle subtended by $P Q$ at the other extremity of the diameter through $P$.

Let $P Q$ and the tangent at $P$ meet the asymptote in $l$ and $L$. Then, if $C V$ he conjugate to $P Q$,
the angle $L P Q=P L C-V l C$

$$
\begin{aligned}
& =L C P-V C l \\
& =V C P \\
& =Q p P .
\end{aligned}
$$

Or thus, let $Q U$ parallel to the tangent at $P$, meet $C P$ produced in $U$.

Then

$$
Q U^{2}=P U \cdot U_{P},
$$

or,

$$
Q U: P U:: U P: U Q .
$$

Therefore the triangles $P Q U, Q U p$ are similar, and the angle $Q p U=P Q U=L P Q$.
137. Prop. VIII. Any chord subtends, at the ends of any diameter, angles which are equal or supplementary.

This theorem divides itself into four cases, which are shewn in the appended figures.

Let $Q R$ be the chord, and $P p$ the diameter. Then, if $L P$ be the tangent at $P$, fig. (1), the angle

$$
L P Q=Q p P
$$

and

$$
\begin{aligned}
L P R & =R p P ; \\
\therefore Q P R & =Q p R .
\end{aligned}
$$

In fig. (2), if $p l$ be the tangent at $p$, parallel to $P L$,

$$
Q p R=Q p l+l p R=Q p l+p P R,
$$

and

$$
\begin{gathered}
Q P R=Q P L+L P R=Q p P+L P R ; \\
\therefore Q p R+Q P R=\operatorname{lp} P+L P p,
\end{gathered}
$$

that is, $Q p R$ and $Q P R$ are together equal to two right angles.

In fig. (3)

$$
\begin{aligned}
Q P R & =Q P L+L P p+p P R \\
& =Q p P+P p l+l p R \\
& =Q p R .
\end{aligned}
$$

In fig. (4)
and

$$
Q P L=Q p P
$$

$$
R P L^{\prime}=R p P
$$

$\therefore Q p R=Q P L+R P L^{\prime}$;

therefore $Q p R$ and $Q P R$ are together equal to two right angles.

Hence it will be seen that when $Q R$, or $Q R$ produced, meet the diameter $P p$ between $P$ and $p$, the angles subtended at $P$ and $p$ are equal; in other cases they are supplementary.
138. Prop. IX. If a rectangular hyperbola circumscribe a triangle, it passes through the orthocentre.

Noтe. The orthocentre is the point of intersection of the perpendiculars from the angular points on the opposite sides.

If $O$ be the orthocentre, the triangles $L O P, L Q R$ are similar, and

$$
\begin{aligned}
& L O: L P:: L Q: L R ; \\
& \therefore L O . L R=L P . L Q .
\end{aligned}
$$

But, if a rectangular hyperbola pass through $P, Q, R$, the diameters parallel to $L R, P Q$ are equal: hence $O$ is a point on the curve.
139. Prop. X. If a rectangular hyperbola circumscribe a triangle, the locus if its centre is the nine-point circle of the triangle.

If $P Q R$ be the triangle, let $L, L^{\prime}$ be the points in which an asymptote meets the sides $P Q, P R$.

Join $C$, the centre of the hyperbola, with $E$ and $F$, the middle points of $P R$ and $P Q$.

Then $C F$ is conjugate to $P Q$, and $C E$ to $P R$; therefore the angle

$$
\begin{aligned}
F C E & =F C L+L^{\prime} C E \\
& =C L F+E L^{\prime} C \\
& =P L L^{\prime}+P L^{\prime} L \\
& =F P E \\
& =F D E,
\end{aligned}
$$

if $D$ be the middle point of $Q R$.
The circle passing through $D, E, F$ therefore passes through $C$; that is, $C$ lies on the nine-point circle.

A similar proof is applicable to the case in which the points $P, Q, R$ lie on the same branch of the hyperbola.
140. The proof of Prop. (xxxiv), Art. (129), appears to fail in this case, since it does not follow, when two diameters are equal, that they are equally inclined to the axes.

It is however obvious that, if a circle intersect an hyperbola, either the four points of intersection are all on one branch of the curve, or there are two on each branch; on the other hand, of two conjugate diameters, or of two diameters at right angles, one meets the curve and the other does not. Hence if chords be drawn parallel to these diameters one chord will meet opposite branches, and the other will meet one branch only ; the cases are therefore distinct, and the proof holds good.

## Examples.

1. A circle is described on the transverse axis as diameter. Prove that if any tangent be drawn to the hyperbola, the straight lines joining the centre of the hyperbola with the point of contact and with the middle point of the chord of intersection of the tangent with the circle, are inclined to the asymptotes at complementary angles.
2. $P C P$ is a transverse diameter, and $Q V$ an ordinate; shew that $Q V$ is the tangent at $Q$ to the circle circumscribing the triangle $P Q p$.
3. If the tangent at $P$ meet the asymptotes in $L$ and $M$, and the normal meet the transverse axis in $G$, a circle can be drawn through $C, L, M$, and $G$, and $L G M$ is a right angle.
4. Find the locus of the middle point of a line cutting off a constant area from the corner of a square.
5. If $A A^{\prime}$ be any diameter of a circle, $P P^{\prime}$ any ordinate to it, then the locus of the intersections of $A P, A^{\prime} P^{\prime}$ is a rectangular hyperbola.
6. If from the extremities of any diameter lines be drawn to any point in the curve, they will be equally inclined to the asymptotes.
7. Given an asymptote and a tangent at a given point, construct a rectangular hyperbola.
8. If $C P, C D$, and $C P^{\prime}, C D^{\prime}$ be two pairs of conjugate semidiameters, prove that the angles $P C P^{\prime}, D C D^{\prime}$ are equal.
9. Focal chords parallel to conjugate diameters are equal.
10. Focal chords at right angles to each other are equal.
11. The points of intersection of an ellipse and a confocal rectangular hyperbola are the extremities of the equi-conjugate diameters of the ellipse.
12. If $C P, C D$ be conjugate semi-diameters, and $P N, D M$ ordinates of any diameter, the triangles $P C N, D C M$ are equal in all respects.
13. The distance of any point from the centre is a geometric mean between its distances from the foci.
14. If $P$ be a point on an equilateral hyperbola, and if the tangent at $Q$ meet $C P$ in $T$, the circle circumscribing $C T Q$ touches the ordinate $Q V$ conjugate to $C P$.
15. If a circle be described on $S S^{\prime}$ as diameter, the tangents at the vertices will intersect the asymptotes in the circumference.
16. If two concentric rectangular hyperbolas be described, the axes of one being the asymptotes of the other, they will intersect at right angles.
17. If the tangents at two points $Q$ and $Q^{\prime}$ meet in $T$, and if $C Q, C Q^{\prime}$ meet these tangents in $R$ and $R^{\prime}$, the circle circumscribing $R T R^{\prime}$ passes through $C$.
18. If from a point $Q$ in the conjugate axis $Q A$ be drawn to the vertex, and $Q R$ parallel to the transverse axis to meet the curve, $Q R=A Q$.
19. Straight lines, passing through a given point, are bounded by two fixed lines at right angles to each other; find the locus of their middle points.
20. Given a point $Q$ and a straight line $A B$, if a line $Q C P$ be drawn cutting $A B$ in $O$, and $P$ be taken in it, so that $P D$ being a perpendicular upon $A B, C D$ may be of constant magnitude, the locus of $P$ is a rectangular hyperbola.
21. Every conic passing through the centres of the four circles which touch the sides of a triangle, is a rectangular hyperbola.
22. Ellipses are inscribed in a given parallelogram, shew that their foci lie on a rectangular hyperbola.
23. If two focal chords be parallel to conjugate diameters, the lines joining their extremities intersect on the asymptotes.
24. If $P, Q$ be two points of a rectangular hyperbola, centre $O$, and $Q N$ the perpendicular let fall on the tangent at $P$, the circle through $O, N$, and $P$ will pass through the middle point of the chord $P, Q$.

Having given the centre, a tangent, and a point of a rectangular hyperbola, construct the asymptotes.
25. If a right-angled triangle be inscribed in the curve, the normal at the right angle is parallel to the hypothenuse.
26. On opposite sides of any chord of a rectangular hyperbola are described equal segments of circles; shew that the four points, in which the circles, to which these segments belong, again meet the hyperbola, are the angular points of a parallelogram.
27. Two lines of given lengths coincide with and move along two fixed lines, in such a manner that a circle can always be drawn through their extremities; the locus of the centre is a rectangular hyperbola.
28. If a rectangular hyperbola, having its asymptotes coincident with the axes of an ellipse, touch the ellipse, the axis of the hyperbola is a mean proportional between the axes of the ellipse.
29. The tangent at a point $P$ of a rectangular hyperbola meets a diameter $Q C^{\prime} Q^{\prime}$ in $T^{\prime}$. Shew that $C Q$ and $T Q^{\prime}$ subtend equal angles at $P$.
30. If $A$ be any point in a rectangular hyperbola, of which $O$ is the centre, $B O C$ the straight line through $O$ at right angles to $O A, D$ any other point in the curve, and $D B, D C$ parallel to the asymptotes, prove that a circle can be drawn through $B, D$, $A$, and $C$.
31. The angle subtended by any chord at the centre is the supplement of the angle between the tangents at the ends of the chord.
32. If two rectangular hyperbolas intersect in $A, B, C, D$; the circles described on $A B, C D$ as diameters intersect each other orthogonally.
33. Prove that the triangle, formed by the tangent at any point and its intercepts on the axes, is similar to the triangle formed by the straight line joining that point with the centre, and the abscissa and ordinate of the point.
34. The angle of inclination of two tangents to a parabola is half a right angle; prove that the locus of their point of intersection is a rectangular hyperbola, having one focus and the corresponding directrix coincident with the focus and directrix of the parabola.
35. $P$ is a point on the curve, and $P M, P N$ are straight lines making equal angles with one of the asymptotes; if $M P$, $N P$ be produced to meet the curve in $P^{\prime}$ and $Q^{\prime}$, then $P^{\prime} Q^{\prime}$ passes through the centre.
36. A circle and a rectangular hyperbola intersect in four points and one of their common chords is a diameter of the hyperbola; shew that the other common chord is a diameter of the circle.
37. $A B$ is a chord of a circle and a diameter of a rectangular hyperbola; $P$ any point on the circle; $A P, B P$, produced if necessary, meet the hyperbola in $Q, Q^{\prime}$, respectively ; the point of intersection of $B Q, A Q^{\prime}$ will be on the circle.
38. $P P^{\prime}$ is any diameter, $Q$ any point on the curve, $P R$, $P^{\prime} R^{\prime}$ are drawn at right angles to $P Q, P^{\prime} Q$ respectively, intersecting the normal at $Q$ in $R, R^{\prime}$; prove that $Q R$ and $Q R^{\prime}$ are equal.
39. Parallel tangents are drawn to a series of confocal ellipses; prove that the locus of the points of contact is a rectangular hyperbola having one of its asymptotes parallel to the tangents.
40. If tangeuts, parallel to a given direction, are drawn to a system of circles passing through two fixed points, the points of contact lie on a rectangular hyperbola.
41. The chords which subtend a right angle at a point $P$ of the curve are all parallel to the normal at $P$.
42. From the point of intersection of the directrix with one of the asymptotes of a rectangular hyperbola a tangent is drawn to the curve and meets the other asymptote in $T$ : shew that $C T^{\prime}$ is equal to the transverse axis.
43. The normals at the ends of two conjugate diameters intersect on the asymptote, and are parallel to another pair of conjugate diameters.
44. If the base $A B$ of a triangle $A B C$ be fixed, and if the difference of the angles at the base is constant, the locus of the vertex is a rectangular hyperbola.
45. The locus of the point of intersection of tangents to an ellipse which make equal angles with the transverse and conjugate axes respectively, and are not at right angles, is a rectangular byperbola whose vertices are the foci of the ellipse.
46. If $O T$ is the tangent at the point $O$ of a rectangular hyperbola, and $P Q$ a chord meeting it at right angles in $T$, the two bisectors of the angle $O C T$ bisect $O P$ and $O Q$.

## CHAPTER VI.

## THE CYLINDER AND THE CONE.

Definition.
141. If a straight line move so as to pass through the circumference of a given circle, and to be perpendicular to the plane of the circle, it traces out a surface called a Right Circular Cylinder. The straight line drawn through the centre of the circle perpendicular to its plane is the Axis of the Cylinder.

It is evident that a section of the surface by a plane perpendicular to the axis is a circle, and that a section by any plane parallel to the axis consists of two parallel lines.
142. Prop. I. Any section of a cylinder by a plane not parallel or perpendicular to the axis is an ellipse.

If $A P A^{\prime}$ be the section, let the plane of the paper be the plane through the axis perpendicular to $A P A^{\prime}$.

Inscribe in the cylinder a sphere touching the cylinder in the circle $E F$ and the plane $A P A^{\prime}$ in the point $S$.

Let the planes $A P A^{\prime}, E F$ intersect in $X K$, and from any point $P$ of the section draw $P K$ perpendicular to $X K$.

Draw through $P$ the circular section $Q P$, cutting $A P A$ in $P N$, so that $P N$ is at right angles to $A A^{\prime}$ and therefore parallel to $X K$.

Let the generating line through $P$ meet the circle $E F$ in $R$; and join $S P$.

Then $P S$ and $P R$ are tangents to the sphere;

$$
\therefore S P=P R=E Q \text {. }
$$

But

$$
\begin{aligned}
E Q: N X & :: A E: A X \\
& :: S A: A X,
\end{aligned}
$$

and

$$
N X=P K
$$

$$
\therefore S P: P K:: S A: A X
$$

Also, $A E$ being less than $A X, S A$ is less than $A X$, and the curve $A P A^{\prime}$ is therefore an ellipse, of which $S$ is the focus and $X K$ the directrix.

If another sphere be inscribed in the cylinder touching $A A^{\prime}$ in $S^{\prime}, S^{\prime}$ is the other focus, and the corresponding directrix is the intersection of the plane of contact $\boldsymbol{E}^{\prime} \boldsymbol{F}^{\prime}$ with $A P A^{\prime}$.

Producing the generating line $R P$ to meet the circle $E^{\prime} F^{\prime}$ in $R^{\prime}$ we observe that $S^{\prime} P=P R^{\prime}$, and therefore

$$
\begin{aligned}
S P+S^{\prime \prime} P & =R R^{\prime}=E E^{\prime} \\
& =A E+A E^{\prime} \\
& =A S+A S^{\prime \prime} ;
\end{aligned}
$$

and

$$
\begin{aligned}
& A S^{\prime}=A E^{\prime}=A^{\prime} F \\
&=A^{\prime} S \\
& \therefore S P+S^{\prime} P=A A^{\prime} .
\end{aligned}
$$

The transverse axis of the section is $A A^{\prime}$ and the conjugate, or minor, axis is evidently a diameter of a circular section.
143. Def. If $O$ be a fixed point in a straight line $O E$ drawn through the centre $E$ of a fixed circle at right angles to the plane of the circle, and if a straight line QOP move so as always to pass through the circumference of the circle, the surface generated by the line QOP is called a Right Circular Cone.

The line $O E$ is called the axis of the cone, the point $O$

is the vertex, and the constant angle $P O E$ is the semivertical angle of the cone.

It is evident that any section by a plane perpendicular to the axis, or parallel to the base of the cone, is a circle ; and that any section by a plane through the vertex consists of two straight lines, the angle between which is greatest and equal to the vertical angle when the plain contains the axis.

Any plane containing the axis is called a Principal Section.
144. Prop. II. The section of a cone by a plane, which is not perpendicular to the asis, and does not pass through the vertex, is either an Ellipse, a Parabola, or an Hyperbola.

Let $U A P$ be the cutting plane, and let the plane of the paper be that principal section which is perpendicular to the plane $U A P ; O V, O A Q$ being the generating lines in the plane of the paper.

Let $A U$ be the intersection of the principal section $V O Q$ by the plane $P A U$ perpendicular to it, and cutting the cone in the curve $A P$.

Inscribe a sphere in the cone, touching the cone in the
circle $E F$ and the plane $A P$ in the point $S$, and let $X K$ be the intersection of the planes $A P, E F$. Then $X K$ is perpendicular to the plane of the paper.

Taking any point $P$ in the curve, join $O P$ cutting the circle $E F$ in $R$, and join $S P$.

Draw through $P$ the circular section $Q P V$ cutting the plane $A P$ in $P N$ which is therefore perpendicular to $A N$ and parallel to $X K$.

Then, $S P$ and $P R$ being tangents to the sphere,

$$
S P=P R=E Q ;
$$

and

$$
\begin{aligned}
E Q: N X & :: A E: A X \\
& :: A S: A X .
\end{aligned}
$$

Also

$$
\begin{gathered}
N X=P K ; \\
\therefore S P: P K:: S A: A X .
\end{gathered}
$$

The curve $A P$ is therefore an Ellipse, Parabola, or Hyperbola, according as $S A$ is less than, equal to, or greater than $A X$. In any case the point $S$ is a focus and the corresponding directrix is the intersection of the plane of the curve with the plane of contact of the sphere.
(1) If $A U$ be parallel to $O V$, the angle

$$
A X E=O F E=O E F=A E X,
$$

and therefore

$$
S A=A E=A X,
$$

and the section is therefore a parabola when the cutting plane is parallel to a generating line, and perpendicular to the principal section which contains the generating line.
(2) Let the line $A U$ meet the curve again in the point $A$ on the same side of the vertex as the point $A$.

Then the angle

$$
\begin{aligned}
A E X & =O F E \\
& >F X A,
\end{aligned}
$$

and therefore that is

$$
\begin{aligned}
& A E<A X, \\
& S A<A X,
\end{aligned}
$$

and the curve is an ellipse.
In this case another sphere can be inscribed in the cone, touching the cone along the circle $E^{\prime} F^{\prime}$ and touching the plane $A P$ in $S^{\prime}$.

It may be shewn as before that $S^{\prime \prime}$ is a focus and that the corresponding directrix is the intersection of the planes $E^{\prime} F^{\prime}, A P A^{\prime}$.
(3) Let the line $U A$ produced meet the cone on the other side of the vertex. The section then consists of two separate branches.

Also the angle $\quad A E X=A^{\prime} F X$

$$
<A X F
$$

and therefore
$A E>A X$,
that is
$A S>A X$,
and the curve $A P$ is one branch of an hyperbola, the other branch being the section $A^{\prime} P^{\prime}$.

Taking $P^{\prime}$ in the other branch the proof is the same as before that

$$
S P^{\prime}: P^{\prime} K^{\prime}:: S A: A X .
$$

In this case a sphere can be inscribed in the other branch of the cone, touching the cone along the circle $E^{\prime} F^{\prime \prime}$, and the plane $U A^{\prime} P^{\prime}$ in $S^{\prime \prime}$, and it can be shewn that $S^{\prime \prime}$ is the other focus of the hyperbola, and that the directrix is the intersection of the cutting plane with the plane of contact $E^{\prime} F^{\prime}$.

Hence the section of a cone by a plane cutting in $A U$ the principal section $V O Q$ perpendicular to it is an Ellipse, Parabola, or Hyperbola, according as the angle EAX is
greater than, equal to, or less than, the vertical angle of the cone.

Further, it is obvious that, if any plane be drawn parallel to the plane $A P$, the ratio of $A E$ to $A X$ is always the same; hence it follows that all parallel sections have the same eccentricity.
145. This method of determining the focus and directrix was published by Mr Pierce Morton, of Trinity College, in the first Volume of the Cambridge Philosophical Transactions.

The method was very nearly obtained by Hamilton, who gave the following construction.

First finding the vertex and focus, $A$ and $S$, take $A E$ along the generating line equal to $A S$, and draw the circular section through $E$; the directrix will be the line of intersection of the plane of the circle with the given plane of section.

Hamilton also demonstrated the equality of $S P$ and $P R$.
146. Prop. III. To prove that, in the case of an elliptic section,

$$
S P+S^{\prime} P=A A^{\prime} .
$$

Taking the 2 nd figure,

$$
\begin{aligned}
& S P=P R \text { and } S^{\prime} P=P R^{\prime} ; \\
& \therefore S P+S^{\prime} P=R R^{\prime}=E E \\
& =A E+A E^{\prime \prime} \\
& =A S+A S^{\prime}
\end{aligned}
$$

But

$$
\begin{aligned}
A^{\prime} S^{\prime \prime} & =A^{\prime} F^{\prime}=F^{\prime} F^{\prime}-A^{\prime} F \\
& =E E^{\prime}-A^{\prime} S
\end{aligned}
$$

also

$$
A^{\prime} S^{\prime}+S S^{\prime}=A^{\prime} S ;
$$

$$
\therefore 2 A^{\prime} S^{\prime}+S S^{\prime}=E E^{\prime}
$$

Similarly $2 A S+S S^{\prime}=E E^{\prime} ;$

$$
\therefore A S^{\prime}=A S
$$

and

$$
A S^{\prime}=A^{\prime} S
$$

152 The Cylinder and the Cone.
Hence

$$
S P+S^{\prime \prime} P=A A^{\prime},
$$

and the transverse, or major axis $=E E^{\prime}$.
In a similar manner it can be shewn that in an hyperbolic section

$$
S^{\prime} P-S P=A A^{\prime}
$$

147. Prop. IV. To shew that, in a parabolic section, $P N^{2}=4 A S . A N$.
Let $A$ be the vertex of the section, and let $A D E$ bs the diameter of the circular section through $A$.

From $D$ let fall $D S$ perpendicular to $A N$;
Then

$$
\begin{aligned}
P N^{2} & =Q N \cdot N Q^{\prime} \\
& =Q N \cdot A E \\
& =4 N L \cdot A D,
\end{aligned}
$$

if $A L$ be perpendicular to $N Q$.
But the triangles $A N L, A D S$ being similar,
and

$$
\begin{gathered}
N L: A N:: A S: A D ; \\
\therefore N L . A D=A N \cdot A S \\
\quad P N^{2}=4 A S \cdot A N .
\end{gathered}
$$

148. Prop. V. To shew that, in an elliptic section, $P N^{2}$ is to $A N . N A^{\prime}$ in a constant ratio.

Draw through $P$ the circular section $Q P Q^{\prime}$, bisect $A A^{\prime}$ in $C$, and draw through $C$ the circular section $E B E^{\prime}$.

Then
and

$$
Q N: A N:: C E: A C,
$$

$N Q^{\prime}: N A^{\prime}:: C E^{\prime}: A^{\prime} C$;

$$
\begin{aligned}
& \therefore Q N . N Q^{\prime}: A N . N A^{\prime}:: E C . C E^{\prime}: A C^{2} \\
& P N^{2}: A N . N A^{\prime}:: E C . C E^{\prime}: A C^{2}
\end{aligned}
$$

or
and, the transverse axis being $A A^{\prime}$, the square of the semiminor axis $=B C^{2}=E C . C E^{\prime}$.

Again, if $A D F$ be perpendicular to the axis, $A D=D F$; and, $A C$ being equal to $C A^{\prime}, C D$ is parallel to $A^{\prime} F$,
and therefore $\quad C E^{\prime}=F D=A D$.
Similarly, $C E=A^{\prime} D^{\prime}$, the perpendicular from $A^{\prime}$ on the axis;

$$
\therefore B C^{2}=A D \cdot A^{\prime} D^{\prime},
$$

that is, the semi-minor axis is a mean proportional between the perpendiculars from the vertices on the axis of the cone.

In exactly the same manner it can be shewn for an hyperbolic section, that

$$
P N^{2}: A N . N A^{\prime}:: C E . C E^{\prime}: A C^{2}
$$

and that and
$C E=A D$,
$C E^{\prime}=A^{\prime} D^{\prime}$.

Hence $B C^{2}=A D \cdot A^{\prime} D^{\prime}, A A^{\prime}$ being the transverse axis.

We observe also that the conjugate axis is equal to the tangent from $C$ to the circular section passing through $C$.

Cor. If $H, H^{\prime}$ be the centres of the two spheres, a circle can be drawn through $A H A^{\prime} H^{\prime}$, and it will be seen that the triangles $A S H, A^{\prime} H^{\prime} D^{\prime}$ are similar, so that

$$
S H: A^{\prime} D^{\prime}:: A H: A^{\prime} H^{\prime}:: A D: S^{\prime} H^{\prime}
$$

and

$$
S H . S^{\prime} H^{\prime}=A D \cdot A^{\prime} D^{\prime} ;
$$

$\therefore$ the semi-conjugate axis is a mean proportional between the radii of the spheres.
149. Prop. VI. The two straight lines in which a cone is intersected by the plane through the vertex parallel to an hyperbolic section are parallel to the asymptotes of the hyperbola.

Taking the preceding figure, let the parallel plane cut the cone in the lines $O G, O G^{\prime}$, and the circular section through $C$ in the line $G L G^{\prime}$, which will be perpendicular to the plane of the paper, and therefore perpendicular to $E E^{\prime}$ and to $O L$.

Hence

$$
G L^{2}=E L \cdot E^{\prime} L .
$$

But

$$
\begin{array}{r}
E L: E C:: O L: A^{\prime} C, \\
E^{\prime} L: E^{\prime} C: O L: A C ; \\
\therefore G L^{2}: E C \cdot E^{\prime} C: O L^{2}: A C^{2}, \\
G L: O L:: B C: A C ;
\end{array}
$$

or
therefore, Art. (98), $O G$ and $O G^{\prime}$ are parallel to the asymptotes of the hyperbola.

Hence for all parallel hyperbolic sections, the asymptotes are parallel to each other.

If the hyperbola be rectangular, the angle $G O G^{\prime}$ is a right angle; but this is evidently not possible if the vertical angle of the cone be less than a right angle.

When the vertical angle of the cone is not less than a right angle, and when $G O G^{\prime}$ is a right angle, $L O G$ is half a right angle, and therefore
and

$$
O L=L G
$$

$$
\text { 2. } O L^{2}=O G^{2}=O E^{2}
$$

and the length $O L$ is easily constructed.
Hence, placing $O L$, and drawing the plane $G O G^{\prime}$ perpendicular to the principal section through $O L$, any section by a plane parallel to $G O G^{\prime}$ is a rectangular hyperbola.
150. Prop. VII. If two straight lines be dravn through any point, parallel to two fixed lines, and intersecting a given cone, the ratio of the rectangles formed by
the segments of the lines will be independent of the position of the point.

Thus, if through $E$, the lines $E P Q, E P^{\prime} Q^{\prime}$ be drawn, parallel to two given lines, and cutting the cone in the

points $P, Q$ and $P^{\prime}, Q^{\prime}$, the ratio of $E P$. $E Q$ to $E P^{\prime} . E Q^{\prime}$ is constant.

Through $O$ draw $O K$ parallel to the given line to which $E P Q$ is parallel, and let the plane through $O K, E P Q$, which contains the generating lines $O P, O Q$, meet the circular section through $E$ in $R$ and $S$, and the plane base in the straight line $D F K$, cutting the circular base in $D$ and $F$.

Then $D F K$ and $E R S$ being sections of parallel planes by a plane are parallel to each other.

Also, $E P Q$ is parallel to $O K$;
Therefore $E R P, O D K$ are similar triangles, as are also $E S Q, O F K$;

$$
\begin{aligned}
\therefore E P & : E R: O K: D K, \\
E Q & : E S: O K: F K
\end{aligned}
$$

and

$$
\begin{gathered}
\text { The Cylinder and the Cone. } \\
\therefore E P \cdot E Q: E R . E S: O K^{2}: D K . F K \\
:: O K^{2}: K T^{2},
\end{gathered}
$$

if $K T$ be the tangent to the circular base from $K$.
If a similar construction be made for $E P^{\prime} Q^{\prime}$ we shall have

$$
E P^{\prime} . E Q^{\prime}: E R^{\prime} . E S^{\prime}:: O K^{\prime 2}: K^{\prime} T^{2} .
$$

But

$$
E R \cdot E S=E R^{\prime} \cdot E S^{\prime} ;
$$

therefore the rectangles $E P . E Q$ and $E P^{\prime} . E Q^{\prime}$ are each in a constant ratio to the same rectangle, and are therefore in a constant ratio to each other.

Since the plane through $E P Q, E P^{\prime} Q^{\prime}$ cuts the cone in an ellipse, parabola, or hyperbola, this theorem includes as particular cases those of Arts. 49, 55, 77, 86, 92, 119 and 129.

The proof is the same if the point $P$ be within the cone, or if one or both of the lines meet opposite branches of the cone.

If the chords be drawn through the centre of the section $P E P^{\prime}$, the rectangles become the squares of the semidiameters.

Hence the parallel diameters of all parallel sections of a cone are proportional to each other.

If the lines move until they become tangents the rectangles then become the squares of the tangents; therefore if a series of points be so taken that the tangents from them are parallel to given lines, these tangents are always in the same proportion. The locus of the point $E$ will be the line of intersection of two fixed planes touching the cone, that is, a fixed line through the vertex.

## Examples.

1. SHew how to cut from a cylinder an ellipse whose eccentricity shall be the same as the ratio of the side of a square to its diagonal.
2. Shew how to cut from a cone an ellipse whose eccentricity is the ratio of one to two.
3. Find the least'angle of a cone from which it is possible to cut an hyperbola, whose eccentricity shall be the ratio of two to one.
4. Shew that all sections of a right cone, made by planes parallel to tangent planes of the cone, are parabolas, and that the foci lie on a cone having with the first a common vertex and axis.
5. The centre of a spherical ball is moveable in a vertical plane which is equidistant from two candles of the same height on a table; find its locus when the two shadows on the ceiling are always just in contact.
6. Prove that all sections of a cone by parallel planes are conics having the same eccentricity.
7. Find the locus of the foci of the sections made by a series of parallel planes.
8. Give a geometrical construction, by which a cone may be cut, so that the section may be an ellipse of given eccentricity.
9. If two plane sections of a right cone be taken, having the same directrix, the foci corresponding to that directrix lie on a straight line which passes through the vertex.
10. Different elliptic sections of a right cone are taken, having equal major axes; shew that the locus of the centres of the sections is a spheroid, and determine in what cases it is oblate or prolate respectively.
11. The vertex of a cone and the centre of a sphere inscribed within it are given in position: a plane section of the cone, at right angles to any generating line of the cone, touches the sphere: prove that the locus of the point of contact is a surface generated by the revolution of a circle, which touches the axis of the cone at the centre of the sphere.
12. Given a right cone and a point within it, there are but two sections which have this point for focus; and the planes of these sections make equal angles with the straight line joining the given point and the vertex of the cone.
13. If the curve formed by the intersection of any plane with a cone be projected upon a plane perpendicular to the axis; prove that the curve of projection will be a conic section having its focus at the point in which the axis meets the plane of projection.
14. An ellipse and an hyperbola are so situated that the vertices of each curve are the foci of the other, and the curves are in planes at right angles to each other. If $P$ be a point on the ellipse, and $Q$ a point on the hyperbola, $S$ the vertex, and $A$ the interior focus of that branch of the hyperbola, then

$$
P Q+A S=P S+A Q
$$

15. The shadow of a ball is cast by a candle on an inclined plane in contact with the ball; prove that, as the candle burns down, the locus of the centre of the shadow will be a straight line.
16. If sections of a right cone be made, perpendicular to a given plane, such that the distance between a focus of a section and that vertex which lies on one of the generating lines in the given plane be constant, prove that the transverse axes, produced if necessary, of all sections will touch one of two fixed circles.
17. If the vertical angle of a cone, vertex $V$, be a right angle, $P$ any point of a parabolic section, and $P N$ perpendicular to the axis of the parabola,

$$
V P=2 A S+A N
$$

$A$ being the vertex and $S$ the focus.
18. If two cones be described touching the same two spheres, the eccentricities of the two sections of them made by the same plane bear to one another a ratio constant for all positions of the plane.
19. If elliptic sections of a cone be made such that the volume betweon the vertex and the section is always the same, the minor axis will be always of the same length.
20. The vertex of any right circular cone which contains a given eilipse will lie on a certain hyperbola, and the axis of the cone will be a tangent to the hyperbola.
21. Different elliptic sections of a right cone are taken such that their minor axes are equal; shew that the locus of their centres is the surface formed by the revolution of an hyperbola about the axis of the cone.
22. If $C, E$ be the centres of the spheres inscribed in a cone, and touching a given section, the sphere described on $C E$ as diameter will intersect the plane in the auxiliary circle of the section.

## CHAPTER VII.

The Similarity of Conics, the Areas of Conics, and the Curvatures of Conics.

## SIMILAR CONICS.

151. Def. Conics which have the same eccentricity are said to be similar to each other.

This definition is justified by the consideration that the character of the conic depends on its eccentricity alone, while the dimensions of all parts of the conic are entirely determined by the distance of the focus from the directrix.

Hence, according to this definition, all parabolas are similar curves.
152. Prop. I. If radii be drawn from the vertices of two parabolas making equal angles with the axes, these radii are always in the same proportion.

Let $A P, a p$ be the radii, $P N$ and $p n$ the ordinates, the angles $P A N$, pan, being equal.

Then

$$
A N: a n:: A P: a p,
$$

and
But
or

$$
P N: p n:: A P: a p
$$

$$
P N^{2}: p n^{2}:: A S . A N: a s . a n
$$

$$
\therefore A P^{2}: a p^{2}:: A S . A P: a s . a p,
$$

$$
A P: a p:: A S: a s .
$$

It can also be shewn that focal radii making equal angles with the axes are always in the same proportion.
153. Prop. II. If two ellipses be similar their axes are in the same proportion, and any other diameters, making equal angles with the respective axes, are in the proportion of the axes.

Let $C A, C B$ be the semi-axes of one ellipse, $c a, c b$ of the other, and $C P, c p$ two radii such that the angle $P C A=p c a$.

Then, since the eccentricities are the same, we have, if $S, s$ be foci,

$$
A C: S C:: a c: s c ;
$$

$$
\begin{gathered}
\therefore A C^{2}: A C^{2}-S C^{2}:: a c^{2}: a c^{2}-s c^{2}, \\
A C^{2}: B C^{2}:: a c^{2}: b c^{2} .
\end{gathered}
$$

Hence it follows, if $P N, p n$ be ordinates, that

$$
P N^{2}: A C^{2}-C N^{2}:: p n^{2}: a c^{2}-c n^{2} ;
$$

but, by similar triangles,

$$
P N: p n:: C N: c n,
$$

therefore $C N^{2}: A C^{2}-C N^{2}:: c n^{2}: a c^{2}-c n^{2}$;
and

$$
C N^{2}: A C^{2}:: c n^{2}: a c^{2}
$$

Hence

$$
\begin{aligned}
& C P: c p:: C N: c n \\
& \text { :: } A C: a c \text {. }
\end{aligned}
$$

So also lines drawn similarly from the foci, or any other corresponding points of the two figures, will be in the ratio of the transverse axes.

Exactly the same demonstration is applicable to the hyperbola, but in this case, if the ratio of $S C$ to $A C$ in two hyperbolas be the same, it follows from Art. (98) that the angle between the asymptotes is the same in both curves.

In the case of hyperbolas we have thus a very simple test of similarity.

## The Areas bounded by Conics.

154. Prop. III. If $A B, A C$ be two tangents to a parabola, the area between the curve and the chord $B C$ is two-thirds of the triangle ABC.
B. c. s.

Draw the tangent $D P E$ parallel to $B C$; then
and

$$
A P=P N,
$$

therefore triangle

$$
B P C=2 A D E .
$$

Again, draw the diameter $D Q M$ meeting $B P$ in $M$.
By the same reasoning, $F Q G$ being the tangent parallel to $B P$, the triangle $P Q B=2 F D G$.

Through $F$ draw the diameter $F R L$, meeting $P Q$ in $L$, and let this process be continued indefinitely.

Then the sum of the triangles within the parabola is double the sum of the triangles without it.

But, since the triangle $B P C$ is half $A B C$, it is greater than half the parabolic area $B Q P C$;

Therefore, Euclid, Bk. xir., the difference between the parabolic area and the sum of the triangles can be made ultimately less than any assignable quantity;

And, the same being true of the outer triangles, it follows that the area between the curve and $B C$ is double of the area between the curve and $A B, A C$, and is therefore two-thirds of the triangle $A B C$.

Cor. Since $P N$ bisects every chord parallel to $B C$ it bisects the parabolic area $B P C$; therefore, completing the parallelogram $P N B U$, the parabolic area $B P N$ is twothirds of the parallelogram $U N$.
155. Prop. IV. The area of an ellipse is to the area of the auxiliary circle in the ratio of the conjugate to the transverse axis.

Draw a series of ordinates, $Q P N, Q^{\prime} P^{\prime} N^{\prime}, \ldots$ near each other, and draw $P R, Q R^{\prime}$ parallel to $A C$.

Then, since
the area

$$
P N: Q N:: B C: A C,
$$

and, this being true for all such areas, the sum of the parallelograms $P N^{\prime}$ is to the sum of the parallelograms $Q N^{\prime}$ as $B C$ to $A C$.

But, if the number be increased indefinitely, the sums of these parallelograms ultimately approximate to the areas of the ellipse and circle.

Hence the ellipse is to the circle in the ratio of $B C$ to $A C$.

The student will find in Newton's 2nd and 3rd Lemmas (Principia, Section 1.) a formal proof of what we have
here assumed as sufficiently obvious, that the sum of the parallelograms $P N$ is ultimately equal to the area of the ellipse.
156. Prop. V. If $P, Q$ be two points of an hyperbola, and if PL, QM parallel to one asymptote meet the other in $L$ and $M$, the hyperbolic sector $C P Q$ is equal to the hyperbolic trapezium PLMQ.

For the triangles $C P L, C Q M$ are equal, and, if $P L$ meet $C Q$ in $R$, it follows that the triangle $C P R=$ the trapezium $L R Q M$; hence, adding to each the area $R P Q$ the theorem is proved.
157. Prop. VI. If points $L, M, N, K$ be taken in an asymptote of an hyperbola, such that

$$
C L: C M:: C N: C K,
$$

and if $L P, M Q, N R, K S$, parallel to the asymptote, meet the curre in $P, Q, R, S$, the hyperbolic areas $C P Q, C R S$ will be equal.

Let $Q R$ and $P S$ produced meet the asymptotes in $F$, $F^{\prime}, G, G^{\prime}$;
then

$$
\begin{gathered}
R F=Q F^{\prime} \text { and } S G=P G^{\prime} . \quad \text { Art. (116) ; } \\
\therefore N F=C M \text { and } K G=C L .
\end{gathered}
$$

Hence

$$
\begin{aligned}
N F: K G & :: C M: C L \\
& :: C K: C N \\
& :: R N: S K,
\end{aligned}
$$

and therefore $S P$ is parallel to $Q R$.

The diameter $C U V$ conjugate to $P S$ bisects all chords parallel to $P S$, and therefore bisects the area $P Q R S$;

also the triangle and
$C P V=C S V$,
$C Q U=C U R$;
therefore taking from $C P V$ and $C S V$ the equal triangles $C Q U, C R U$, and the equal areas $P Q U V, S R U V$, the remaining areas, which are the hyperbolic sectors $C P Q$, $C R S$, are equal.

Cor. Hence if a series of points, $L, M, N, \ldots$ be taken such that $C L, C M, C N, C K, \ldots$ are in continued proportion, it follows that the hyperbolic sectors $C P Q, C Q R, C R S, \& \mathrm{c}$. will be all equal.

It will be noticed in this case that the tangent at $Q$ will be parallel to $P R$, the tangent at $R$ parallel to $Q S$, and so also for the rest.

## The Curvature of Conics.

158. Def. If a circle touch a conic at a point $P$, and pass through another point $Q$ of the conic, and if the point $Q$ move near to, and ultimately coincide with $P$, the circle in its ultimate condition is called the circle of curvature at $P$.

Prop. VII. The chord of intersection of a conic with the circle of curvature at any point is inclined to the axis at the same angle as a tangent at the point.

It has been shewn that, if a circle intersect a conic in four points $P, Q, R, V$, the chords $P Q, R V$ are equally inclined to the axis.

Let $P$ and $Q$ coincide with each other; then the tangent at $P$ and the chord $R V$ are equally inclined to the axis.

Let the point $V$ now approach to and coincide with $P$; the circle becomes the circle of curvature at $P$, and the chord $V R$ becomes $P R$ the chord of intersection.

Hence $P R$ and the tangent at $P$ are equally inclined to the axis.
159. Prop. VIII. If the tangent at any point $P$ of a parabola meet the axis in T, and if the circle of curvature at $P$ meet the curve in $Q$,

$$
P Q=4 . P T .
$$

Draw the ordinate $P N P^{\prime}$; then taking the figure of the next article, $T P^{\prime}$ is the tangent at $P^{\prime}$, and the angle $P^{\prime} T F=P T F=P F T$; therefore $P Q$ is parallel to $T P^{\prime}$, and is bisected by the diameter $P^{\prime} E$.

Hence

$$
\begin{aligned}
P Q=2 \cdot P E & =4 P^{\prime} T \\
& =4 P T .
\end{aligned}
$$

160. Prop. IX. To find the chord of curvature through the focus and the diameter of curvature at any point of a parabola.

Let the circle meet PS produced in $V$, and the normal $P G$, produced, in $O$.

$$
\text { The angle } \quad \begin{aligned}
P F S & =P T S=S P T \\
& =P Q V,
\end{aligned}
$$

since $P T$ is a tangent to the circle.
Therefore $Q V$ is parallel to the axis, and

$$
P V: S P:: P Q: P F .
$$

Hence

$$
P V=4 . S P
$$

Again, the angle $P O Q=P V Q=P S N$;

$$
\therefore P O: P Q:: S P: P N,
$$

or

$$
P O: S P:: 4 P T: P N
$$

$$
:: 4 S P: S Y
$$

if $S Y$ be perpendicular to $P T$.
Cor. 1. Since the normal bisects the angle between $S P$ and the diameter through $P$, it follows that the chord of curvature parallel to the axis is $4 S P$.

Cor. 2. The diameter of curvature, $P O$, may also be expressed as follows:

Let $G L$ be the perpendicular from $G$ on $S P$; then $P L$ $=$ the semi-latus rectum $=2 A S$.

Also $P V O$ being a right angle,

$$
\begin{aligned}
P O: P G & :: P V: P L \\
& :: 4 S P: P L \\
& :: 4 S P . P L: P L^{2},
\end{aligned}
$$

but

$$
\begin{gathered}
4 S P \cdot P L=8 S P \cdot A S=8 S Y^{2}=2 P G^{2} ; \\
\therefore P O: P G: 2 P G^{2}: P L^{2} .
\end{gathered}
$$

161. Prop. X. If the chord of intersection, $P Q$, of an ellipse, or hyperbola, with the circle of curvature at $P$, meet $C D$, the semi-diameter conjugate to $C P$, in $K$,

$$
P Q . P K=2 C D^{2} .
$$

Drawing the ordinate $P N P^{\prime}$, the tangent at $P^{\prime}$ is parallel to $P Q$, as in the parabola, and $P Q$ is therefore bisected in $V$, by the diameter $C P^{\prime}$.

Let $P Q$ meet the axes in $U$ and $U^{\prime}$; then, $U^{\prime} C$ being parallel to $P P^{\prime}$,

$$
\begin{aligned}
P V: P U^{\prime} & :: V P^{\prime}: C P^{\prime} \\
& :: U T: C T
\end{aligned}
$$

since

$$
P U, P^{\prime} T \text { are parallel. }
$$

Also

$$
U T: C T:: P U: P K
$$

$$
\therefore P V: P U^{\prime}:: P U: P K .
$$

Hence $P V \cdot P K=P U \cdot P U^{\prime}=P T \cdot P T^{\prime}=C D^{2}$, observing that $P U=P T$, and $P U^{\prime}=P T^{\prime}$, by the theorem of Art. (158);
and
$\therefore P Q . P K=2 C D^{2}$.

162. Prop. XI. If the chord of curvature $P Q^{\prime}$, of an ellipse or hyperbola in any direction, meet $C D$ in $K^{\prime}$,

$$
P Q^{\prime} \cdot P K^{\prime}=2 . C D^{2} .
$$

Let $P O$ be the diameter of curvature meeting $C D$ in $F$; then $P Q O, P Q^{\prime} O$ are right angles, and a circle can be drawn through $Q^{\prime} K^{\prime} F O$;

$$
\begin{aligned}
\therefore P Q^{\prime} \cdot P K^{\prime} & =P F \cdot P O \\
& =P K \cdot P Q=2 \cdot C D^{2} .
\end{aligned}
$$

Cor. 1. Hence $P O$ being the diameter of curvature,

$$
P F . P O=2 . C D^{2} .
$$

Cor. 2. If $P Q^{\prime}$ pass through the focus,

$$
P K^{\prime}=A C,
$$

and

$$
P Q^{\prime} \cdot A C=2 . C D^{2} .
$$

Cor. 3. If $P Q^{\prime}$ pass through the centre,

$$
P Q^{\prime} . C P=2 . C D^{2} .
$$

163. We can also express the diameter of curvature as follows :
$P G$ being the normal, let $G L$ be perpendicular to $S P$. and let $P R$ be the chord of curvature through $S$.

Then $G L$ is parallel to $O R$,
and

$$
\begin{aligned}
P O: P G & :: P R: P L \\
& :: P R . P L: P L^{2} .
\end{aligned}
$$

But

$$
P R . A C=2 . C D^{2} ;
$$

$$
\therefore P R: A C:: 2 . C D^{2}: A C^{2}
$$

$$
:: 2 . P G^{2}: B C^{2}
$$

and

$$
P R . P L: A C . P L:: 2 . P G^{2}: B C^{2} .
$$

But, $P L$ being equal to the semi-latus rectum,
and

$$
\begin{gathered}
P L . A C=B C^{2} ; \\
\therefore P R . P L=2 \cdot P G^{2}, \\
P O: P G:: 2 P G^{2}: P L^{2} .
\end{gathered}
$$

Hence, in any conic, the radius of curvature at any point is to the normal at the point as the square of the normal to the square of the semi-latus rectum.

## EXAMPLES.

1. The radius of curvature at the extremity of the latus rectum of a parabola is equal to twice the normal.
2. The circle of curvature at the end of the latus rectum intersects the parabola on the normal at that point.
3. The chord of curvature at a point $P$ in the parabola passing through the vertex $A$ is to $4 P Y$ :: $P Y: A P$.
4. The circle of curvature at a point $P$ in a parabola cuts off from the diameter at $P$ a portion equal to the parameter of that diameter.
5. $\quad P$ and $p$ are points on a parabola on the same side of the axis; $P N$ and $p n$ are perpendiculars on the axis; the normals at $P$ and $p$ meet at a point $Q$ : shew that the distance of $Q$ from the axis is to $2 . P N$ in the ratio of the rectangle $p n(P N+p n)$ to the square on the latus rectum.

Deduce an expression for the radius of curvature at any point of a parabola.
6. If $P$ be a point of an ellipse equidistant from the axis minor and one of the directrices, prove that the circle of curvature at $P$ will pass through one of the foci.
7. The chord of curvature through the focus, at any point, is equal to the focal chord parallel to the tangent at the point.
8. Prove that the locus of the middle points of the common chords of a given parabola and its circles of curvature is a parabola, and that the envelope of the chords is also a parabola.
9. The circles of curvature at the extremities $P, D$ of two conjugate diameters of an ellipse meet the ellipse again in $Q, R$, respectively, shew that $P R$ is parallel to $D Q$.
10. In the rectangular hyperbola, the radius of curvature at a point $P$ varies as $C P^{3}$.
11. The tangent at a point $P$ of an ellipse whose centre is $C$ meets the axes in $T$ and $t$; if $C P$ produced meet in $L$ the circle described about the triangle $T C t$, shew that $P L$ is half the chord of curvature at $P$ in the direction of $C$, and that the rectangle contained by $C P, C L$, is constant.
12. If $P$ be a point on a conic, $Q$ a point near it, and if $Q E$, perpendicular to $P Q$, meet the normal at $P$ in $E$, then ultimately when $Q$ coincides with $P, P E$ is the diameter of curvature at $P$.
13. Prove that the ultimate point of intersection of consecutive normals is the centre of curvature.
14. If a tangent be drawn from any point of a parabola to the circle of curvature at the vertex, the length of the tangent will be equal to the abscissa of the point measured along the axis.
15. The circle of curvature at a point where the conjugate diameters are equal, meets the ellipse again at the extremity of the diameter.
16. Find the points at which the radius of curvature is a mean proportional between the semi-major and semi-minor axes of an ellipse.
17. The chord of curvature at $P$ perpendicular to the major axis is to $P M$, the ordinate at $P,: 2 . C D^{2}: B C^{2}$.
18. Prove that there is a point $P$ on an ellipse such that if the normal at $P$ meet the ellipse in $Q, P Q$ is a chord of the circle of curvature at $P$, and find its position.
19. If $S P$ be the focal distance of a point $P$ of a parabola, and $S Q$, perpendicular to $S P$, meet the normal at $P$ in $Q, P Q$ is half the radius of curvature at $P$.
20. The chord of curvature at a point $P$ of a rectangularhyperbola, perpendicular to an asymptote, is to $C D:: C D: 2 . P N$, where $P N$ is the distance of $P$ from the asymptote.
21. If $G$ be the foot of the normal at a point $P$ of an ellipse, and $G K$, perpendicular to $P G$, meet $C P$ in $K$, then $K E$, parallel to the axis minor, will meet $P G$ in the centre of curvature at $P$.
22. If the normel at a point $P$ of a parabola meet the directrix in $L$, the radius of curvature at $P$ is equal to 2. $P L$.
23. The normal at any point $P$ of a rectangular hyperbola meets the curve again in $Q$; shew that $P Q$ is equal to the diameter of curvature at $P$.
24. In the rectangular hyperbola, if $C P$ be produced to $Q$, so that $P Q=C P$, and $Q O$ be drawn perpendicular to $C Q$ to intersect the normal in $O, O$ is the centre of curvature at $P$.
25. If $S$ and $H$ be the foci of an ellipse, $B$ the extremity of the axis minor, a circle described through $S, H$ and $B$, will cut the minor axis in the centre of curvature at $B$.
26. The tangent at any point $P$ in an ellipse, of which $S$ and $H$ are the foci, meets the axis major in $T$, and $T Q R$ bisects $H P$ in $Q$ and meets $S P$ in $R$; prove that $P R$ is one-fourth of the chord of curvature at $P$ through $S$.
27. An ellipse, a parabola, and an hyperbola, have the same vertex and the same focus; shew that the curvature, at the vertex, of the parabola is greater than that of the hyperbola, and less than that of the ellipse.
28. The circle of curvature of an ellipse at $P$ passes through the focus $S$, and $S E$ is drawn parallel to the tangent at $P$ to meet in $E$ the diamcter through $P$; shew that it divides the diameter in the ratio of $3: 1$.
29. The circle of curvature at a point of an ellipse cuts the curve in $Q$; the tangent at $P$ is met by the other common tangent, which touches the curves at $E$ and $F$, in $T$; if $P Q$ meet $T E F$ in $O, T E O F$ is cut harmonically.
30. If the common tangents to an ellipse and a concentric circle are parallel to the common diameters, prove that the areas of the ellipse and circle are equal.
31. If $E$ is the centre of curvature at the point $P$ of a parabola,

$$
S E^{2}+3 \cdot S P^{2}=P E^{2} .
$$

32. Find the locus of the foci of the parabolas which have a given circle as circle of curvature.

## CHAPTER VIII.

## PROJECTIONS.

164. Def. The projection of a point on a plane is the foot of the perpendicular let fall from the point on the plane.

If from all points of a given curve perpendiculars be let fall on a plane, the curve formed by the feet of the perpendiculars is the projection of the given curve.

The projection of a straight line is also a straight line, for it is the line of intersection with the given plane of a plane through the line perpendicular to the given plane.

Parallel straight lines project into parallel lines, for the projections are the lines of intersection of parallel planes with the given plane.
165. Prop. I. Parallel straight lines, of finite lengths, are projected in the same ratio.

That is, if $a b, p q$ be the projections of the parallel lines $A B, P Q$,

$$
a b: A B:: p q: P Q .
$$

For, drawing $A C$ parallel to $a b$ and meeting $B b$ in $C$, and $P R$ parallel to $p q$ and meeting $Q q$ in $R, A B C$ and $P Q R$ are similar triangles; therefore
and

$$
\begin{array}{r}
A C: A B:: P R: P Q \\
A C=a b, P R=p q .
\end{array}
$$

166. Prop. II. The projection of the tangent to a curve at any point is the tangent to the projection of the curve at the projection of the point.

For if $p, q$ be the projections of the two points $P, Q$ of a curve, the line $p q$ is the projection of the line $P Q$, and when the line $P Q$ turns round $P$ until $Q$ coincides with $P$, $p q$ turns round $p$ until $q$ coincides with $p$, and the ultimate position of $p q$ is the tangent at $p$.
167. Prop. III. The projection of a circle is an ellipse.

Let $a b a^{\prime}$ be the projection of the circle $A B A^{\prime}$.

Take a chord $P Q$ parallel to the plane of projection, then its projection $p q=P Q$.

Let the diameter $A N A^{\prime}$ perpendicular to $P Q$ meet in $F$ the plane of projection, and let $a a^{\prime} F$ be the projection of $A A^{\prime} F$.

Then $a a^{\prime}$ bisects $p q$ at right angles in the point $n$, and

$$
\begin{gathered}
a n: A N:: a F: A F, \\
a^{\prime} n: A^{\prime} N:: a F: A F ;
\end{gathered}
$$

$$
\therefore A N . N A^{\prime}: a n . n a^{\prime}:: A F^{2}: a F^{2} ;
$$

but

$$
A N \cdot N A^{\prime}=P N^{2}=p n^{2}
$$

$$
\therefore p n^{2}: a n \cdot n a^{\prime}:: A F^{2}: a F^{2}
$$

and the curve apa' is an ellipse, having its axes in the ratio of

$$
a F: A F, \text { or of } a a^{\prime}: A A^{\prime} .
$$

Moreover, since we can place the circle so as to make the ratio of $a a^{\prime}$ to $A A^{\prime}$ whatever we please, an ellipse of any eccentricity can be obtained.

In this demonstration we have assumed only the property of the principal diameters of an ellipse. Properties of other diameters can be obtained by help of the preceding theorems, as in the following instances.
168. Prop. IV. The locus of the middle points of parallel chords of an ellipse is a straight line.

For, projecting a circle, the parallel chords of the ellipse are the projections of parallel chords of the circle, and as the middle points of these latter lie in a diameter of the circle, the middle points of the chords of the ellipse lie in the projection of the diameter which is a straight line, and is a diameter of the ellipse.

Moreover, the diameter of the circle is perpendicular to the chords it bisects ; hence

Perpendicular diameters of a circle project into conjugate diameters of an ellipse.
169. Prop. V. If two intersecting chords of an ellipse be parallel to fixed lines, the ratio of the rectangles contained by their segments is constant.

Let $O P Q, O R S$ be two chords of a circle, parallel to fixed lines, and opq, ors their projections.

Then $O P . O Q$ is to $O p . O Q$ in a constant ratio, and $O R . O S$ is to or . os in a constant ratio; but

$$
O P . O Q=O R . O S
$$

Therefore $o p$. oq is to or. os in a constant ratio; and opq, ors are parallel to fixed lines.
170. Prop. VI. If $q v q^{\prime}$ be a double ordinate of a diameter $c p$, and if the tangent at $q$ meet $c p$ produced in $t$,

$$
c v . c t=c p^{2} .
$$

The lines $q v q^{\prime}$ and $c p$ are the projections of a chord $Q V Q^{\prime}$ of a circle which is bisected by a diameter $C P$, and $t$ is the projection of $T$ the point in which the tangent at $Q$ meets $C P$ produced.

But, in the oircle,
or

$$
C V \cdot C T=C P^{2}
$$

$$
C V: C P:: C P: C T
$$

and, these lines being projected in the same ratio, it follows that
or

$$
\begin{gathered}
c v: c p:: c p: c t, \\
c v . c t=c p^{2} .
\end{gathered}
$$

Hence it follows that tangents to an ellipse at the ends of any chord meet in the diameter conjugate to the chord.

The preceding will serve as sufficient illustrations of the application of the method.
171. Prop. VII. An ellipse can be projected into a circle.

This is really the converse of Art. (167), but we give a construction for the purpose.

Draw a plane through $A A^{\prime}$, the transverse axis, perpendicular to the plane of the ellipse, and in this plane describe a circle on $A A^{\prime}$ as diameter. Also take the chord $A D$, equal to the conjugate axis, and join $A^{\prime} D$, which is perpendicular to $A D$.

Through $A D$ draw a plane perpendicular to $A^{\prime} D$, and project a principal chord $P N P^{\prime}$ on this plane.
B. c.s.

Then $\quad P N^{2}: A N . N A^{\prime}:: B C^{2}: A C^{2}$.
But
$P N=p n$,
$A n: A N:: A D: A A^{\prime}$ :: BC : AC,
and $D n: A^{\prime} N:: B C: A C$.
Hence $A n . n D: A N . N A^{\prime}: B C^{2}: A C^{2}$,
and therefore $\quad p n^{2}=A n . n D$,
and the projection $A p D$ is a circle.
This theorem, in the same manner as that of Art. (167), may be employed in deducing properties of oblique diameters and oblique chords of an ellipse.
172. Prop. VII. The projection of a parabola is a parabola.

For if $P N P^{\prime}$ be a principal chord, bisected by the axis $A N$, the projection $p n p^{\prime}$ will be bisected by the projection an.

Moreover $p n: P N$ will be a constant ratio, as also will be an : AN.

And $\quad P N^{2}=4 A S . A N$.
Hence $p n^{2}$ will be to $4 A S$. an in a constant ratio, and the projection is a parabola, the tangent at $a$ being parallel to $p n$.
173. Prop. VIII. An hyperbola can be always projected into a rectangular hyperbola.

For the asymptotes can be projected into two straight lines $c l, c l^{\prime}$ at right angles, and if $P M, P N$ be parallels to the asymptotes from a point $P$ of the curve, $P M . P N$ is constant.

But $p m: P M$ and $p n: P N$ are constant ratios;
$\therefore p m . p n$ is constant.
And since $p m$ and $p n$ are perpendicular respectively to $c l$ and $c l^{\prime}$, it follows that the projection is a rectangular hyperbola.

The same proof evidently shews that any projection of an hyperbola is also an hyperbola.

The explanations of this chapter apply to a particular
case only of the general method of projections; in strictness we should have defined the method as the method of orthogonal projections.

## EXAMPLES.

1. Prove by the method of projections the theorems of Arts. $65,70,71,73,74,75,77,78,81,83,84$, and 86.
2. A parallelogram is inscribed in a given ellipse; shew that its sides are parallel to conjugate diameters, and find its greatest area.
3. $T P, T Q$ are tangents to an ellipse, and $C P^{\prime}, C Q^{\prime}$ are parallel semidiameters; $P Q$ is parallel to $P^{\prime} Q^{\prime}$.
4. Determine the greatest triangle which can be inscribed in an ellipse having an angular point fixed at a point in its perimeter.
5. If a straight line meet two concentric, similar, and similarly situated ellipses, the portions intercepted between the curves are equal.
6. Find the locus of the point of intersection of the tangents at the extremities of pairs of conjugate diameters of an ellipse.
7. Find the locus of the middle points of the lines joining the extremities of conjugate diameters.
8. If a tangent be drawn at the extremity of the major axis meeting two equal conjugate diameters $C P, C D$ produced in $T$ and $t$; then $P D^{2}=2 A I^{2}$.
9. If a chord $A Q$ drawn from the vertex be produced to meet the minor axis in $O$, and $C P$ be a semidiameter parallel to it, then $A Q . A O=2 C P^{2}$.
10. $O Q, O Q^{\prime}$ are tangents to an ellipse from an external point $O$, and $O R$ is a diagonal of the parallelogram of which $O Q$, $O Q^{\prime}$ are adjacent sides; prove that if $R$ be on the ellipse, $O$ will lie on a similar and similarly situated concentric ellipse.
11. A parallelogram is inscribed in an ellipse, and from any point on the ellipse two straight lines are drawn parallel to the sides of the parallelogram; prove that the rectangles under the segments of these straight lines, made by the sides of the paraltelogram, will be to one another in a constant ratio.
12. A parallelogram circumscribes an ellipse, touching the curve at the extremities of conjugate diameters, and another parallelogram is formed by joining the points where its diagonals meet the ellipse : prove that the area of the inner parallelogram is half that of the outer one.

If four similar and similarly situated ellipses be inscribed in the spaces between the outer parallelogram and the curve, prove that their centres lie in a similar and similarly situated ellipse.
13. If a parallelogram be inscribed in an ellipse, so that the diameter bisecting two opposite sides is always divided by either side in a constant ratio, its area will be constant.
14. If a parallelogram circumscribe an ellipse, and if one of its diagonals bear a constant ratio to the diameter it contains, the area of the parallelogram will be constant.
15. About a given triangle $P Q R$ is circumscribed an ellipse, having for centre the point of intersection ( $C$ ) of the lines from $P, Q, R$ bisecting the opposite sides, and $P C, Q C, R C$ are produced to meet the curve in $P^{\prime}, Q^{\prime}, R^{\prime}$; shew that, if tangents be drawn at these points, the triangle so formed will be similar to $P Q R$, and four times as great.
16. The locus of the middle points of all chords of an ellipse which pass through a fixed point is an ellipse similar and similarly situated to the given ellipse, and with its centre in the middle point of the line joining the given point and the centre of the given ellipse.
17. Prove that an ellipse can be inscribed in a parallelogram so as to touch the middle points of the four sides, and that it is the greatest of all inscribed ellipses.
18. A polygon of a given number of sides circumscribes an ellipse. Prove that, when its area is a minimum, any side is parallel to the line joining the points of contact of the two adjacent sides.
19. The greatest triangle which can be inscribed in an ellipse has one of its sides bisected by a diameter of the ellipse, and the others cut in points of trisection by the conjugate diameter.
20. $A B$ is a given chord of an ellipse, and $C$ any point in the ellipse; shew that the locus of the point of intersection of lines drawn from $A, B, C$ to the middle points of the opposite sides of the triangle $A B C$ is a similar ellipse.
21. $C P, C D$ are conjugate semidiameters of an ellipse ; if an ellipse, similar and similarly situated to the given ellipse, be described on $P D$ as diameter, it will pass through the centre of the given ellipse.
22. If an hyperbola and its conjugate are described having a pair of conjugate diameters of an ellipse for asymptotes, and cutting the ellipse in the points $a, b, c, d$ taken in order, shew that the diameters $O a, O 6$, and $O b, O d$ are conjugate diameters in the ellipse; and also that $O a, O d$, and $O b, O c$ are conjugate diameters in the hyperbolas.
23. $Q$ is a point in one asymptote, and $q$ in the other. If $Q q$ move parallel to itself, find the locus of intersection of tangents to the hyperbola from $Q$ and $q$.
24. $P T, p t$ are tangents at the extremities of any diameter $P p$ of an ellipse; any other diameter meets $P T$ in $T$ and its conjugate meets $p t$ in $t$; also any tangent meets $P T$ in $T^{\prime \prime}$ and $p t$ in $t^{\prime}$; shew that $P T: P T^{\prime}:: p t^{\prime}: p t$.
25. From the ends $P, D$ of conjugate diameters of an ellipse lines are drawn parallel to any tangent line; from the centre $C$ any line is drawn cutting these lines and the tangent in $p, d, t$, respectively; prove that $C p^{2}+C d^{2}=C t^{2}$.
26. If $C P, C D$ be conjugate diameters of an ellipse, and if $B P, B D$ be joined, and also $A D, A^{\prime} P$, these latter intersecting in $O$, the figure $B D O P$ will be a parallelogram.
27. $T$ is a point on the tangent at a point $P$ of an ellipse, so that a perpendicular from $T$ on the focal distance $S P$ is of constant length; shew that the locus of $T$ is a similar, similarly situated and concentric ellipse.

## CHAPTER IX.

## OF CONICS IN GENERAL.

The Construction of a Conic.
174. The method of construction, given in Chapter I., can be extended in the following manner.

Let $f S n$ be any straight line drawn through the focus

$S$, and draw $A x$ from the vertex parallel to $f S$, and meeting the directrix in $x$.

Divide the line $f S n$ in $a$ and $a^{\prime}$ so that

$$
S a: a f:: S a^{\prime}: a^{\prime} f:: S A: A x \text {; }
$$

then $a$ and $a^{\prime}$ are points on the curve, for if $a k$ be the perpendicular on the directrix,

$$
a k: a f:: A X: A x
$$

and therefore $\quad S a: a k:: S A: A X$.

Take any point $e$ in the directrix, draw the lines $e S l$, ea through $S$ and $a$, and draw $S P$ making the angle $P S b$ equal to $l S n$.

Through $P$ draw $F P l$ parallel to $f S$, and meeting $e S$ produced in $l$, then

$$
\begin{gathered}
P l=S P, \\
P l: P F:: S a: a f ; \\
\therefore S P: P F:: S a: a f, \\
S P: P K: S a: a k ;
\end{gathered}
$$ and

and
therefore $P$ is a point in the curve.
The other point of the curve in the line $F P$ may be found as in Art. 9.
175. The construction for the point (a) gives a simple proof that the tangent at the vertex is perpendicular to the axis. For when the angle $A S a$ is diminished, $S a$ approaches to equality with $S A$, and therefore the angle $a A S$ is ultimately a right angle.
176. Prop. I. To find the points in which a given straight line is intersected by a conic of which the focus, the directrix, and the eccentricity are given.

Let $F P P^{\prime}$ be the straight line, and draw $A x$ parallel to it. Join $F S$, and find the points $D$ and $E$ such that

$$
S D: D F:: S E: E F:: S A: A x
$$

Describe the circle on $D E$ as diameter, and let it intersect the given line in $P$ and $P^{\prime}$.

Join $D P, E P$ and draw $S G, F H$ at right angles to $E P$.
Then $D P E$, being the angle in a semicircle, is a right angle, and $D P$ is parallel to $S G$ and $F H$.

Hence

$$
\begin{aligned}
S G: F H & :: S E: E F \\
& :: S D: D F \\
& :: P G: P H
\end{aligned}
$$

therefore the angles $S P G, F P H$ are equal, and therefore $P D$ bisects the angle $S P F$.

Hence $S P: P F:: S D: D F:: S A: A x$, and $P$ is a point in the curve.

Similarly $P^{\prime}$ is also a point in the curve, and the perpendicular from $O$, the centre of the circle, on $F P P^{\prime}$ meets it in $V$, the middle point of the chord $P P^{\prime}$.

Since

$$
\begin{array}{r}
S E: E F:: S A: A x \\
S D: D F:: S A: A x \\
\therefore S E-S D: D E:: S A: A x \\
S O: O D:: S A: A x
\end{array}
$$

a relation analogous to

$$
S C: A C:: S A: A X
$$

We have already shewn, for each conic, that the middle points of parallel chords lie in a straight line; the following article contains a proof of the theorem which includes all the three cases.
177. Prop II. To find the locus of the middle points of a system of parallel chords.

Let $P^{\prime} P$ one of the chords be produced to meet the directrix in $F$, draw $A x$ parallel to $F P$, and divide $F S$ so that

$$
S D: D F:: S E: E F:: S A: A x
$$

then, as in the preceding article, the perpendicular $O V$ upon $P P^{\prime}$ from $O$ the middle point of $D E$, bisects $P P^{\prime}$.

Draw the parallel focal chord $a S a^{\prime}$; then $O c$ parallel to the directrix bisects $a a^{\prime}$ in $c$. Also draw $S G$ perpendicular to the chords, and meeting the directrix in $G$.

Then, if $O V$ meet $a a^{\prime}$ in $n$,

$$
\begin{aligned}
V n: n O & :: S F: S O \\
& :: S f: S c,
\end{aligned}
$$

and, since $n c O, S G f$ are similar triangles,

$$
\begin{array}{r}
n O: n c:: S G: S f ; \\
\therefore V n: n c:: S G: S c,
\end{array}
$$

and the line $V c$ passes through $G$.
The straight line $G c$ is therefore the locus of the middle points of all chords parallel to $a S a^{\prime}$.

The ends of the diameter $G C$ may be found by the construction of the preceding article.

Cor. When the conic is a parabola, $S A=A X$,
and

$$
\begin{aligned}
S a: a f & :: A X: A x \\
& :: S X: S f .
\end{aligned}
$$

So
and

$$
a c: c f:: S X: S f
$$

Hence

$$
\begin{aligned}
S c: c f & :: S X^{2}: S f^{2} \\
& :: G X \cdot X f: G f \cdot f X \\
& :: G X: G f ;
\end{aligned}
$$

and therefore $G c$ is parallel to $S X$, that is, the middle points of parallel chords of a parabola lie in a straight line parallel to the axis.

178. Prop. III. To find the locus of the middle points of all focal chords of a conic.

Taking the case of a central conic, and referring to the figure of the preceding article, let $O c$ meet $S C$ in $N$ :
then

$$
\begin{aligned}
c N: N S & :: f X: S X, \\
c N: N C & :: G X: C X \\
\therefore c N^{2}: S N . N C & : \\
& :: S X \cdot G X: S X . C X \\
& S X . C X .
\end{aligned}
$$

and

Hence it follows that the locus of $c$ is an ellipse of which $S C$ is the transverse axis, and such that the squares of its axes are as $S X: C X$, or, Cor. Art. (59), as

$$
B C^{2}: A C^{2} .
$$

Hence the locus of $c$ is similar to the conic itself.

## EXAMPLES.

1. If an ordinate, $P N P^{\prime}$, to the transverse axis meet the tangent at the end of the latus rectum in $T$,

$$
\begin{aligned}
T P . T P^{\prime} & =S N^{2} . \\
S P & =T N .
\end{aligned}
$$

Shew also that
2. A focal chord $P S Q$ of a conic section is produced to meet the directrix in $K$, and $K M, K N$ are drawn through the feet of the ordinates $P M, Q V$ of $P$ and $Q$. If $K N$ produced meet $P N$ produced in $R$, prove that

$$
P R=P M .
$$

3. Focal chords of an ellipse or hyperbola are in the ratio of the squares on the parallel diameters.
4. The tangents at $P$ and $Q$, two points in a conic, intersect in $T$; if through $P, Q$, chords be drawn parallel to the tangents at $Q$ and $P$, and intersecting the conic in $p$ and $q$ respectively, and if tangents at $p$ and $q$ meet in $T$, shew that $T^{\prime} t$ is a diameter.
5. Two tangents $T P, T Q$ are drawn to a conic intersecting the directrix in $P^{\prime}, Q^{\prime}$.

If the chord $P Q$ cut the directrix in $R$, prove that

$$
S P^{\prime}: S Q^{\prime}:: R P^{\prime}: R Q^{\prime} .
$$

6. Tangents from a point $T$ touch the curve at $P$ and $Q$; if $P Q$ meet the directrices in $R$ and $R^{\prime}, P R$ and $Q R^{\prime}$ subtend equal angles at $T$.
7. The chord of a conic $P P^{\prime}$ meets the directrix in $K$, and the tangents at $P$ and $P^{\prime}$ meet in $T$; if $R K R^{\prime}$, parallel to $S T^{\prime}$, meet the tangents in $R$ and $R^{\prime}$,

$$
K R=K R^{\prime}
$$

8. The tangents at $P$ and $P^{\prime}$, intersecting in $T$, meet the latus rectum in $D$ and $D^{\prime}$; prove that the lines through $D$ and $D^{\prime}$, respectively perpendicular to $S P$ and $S P^{\prime}$, intersect in $S T$.
9. $P S P^{\prime}$ is a focal chord; shew that any line through $S$ is divided harmonically by the directrix and the tangents at $P$ and $P^{\prime}$.
10. Having given a focus, a tangent, and the eccentricity of a conic section; prove that the locus of its centre is a circle.
11. If $P, Q$ be two points on a conic, and $p, q$ two points on the directrix such that $p q$ subtends at the focus half the angle subtended by $P Q$, either $P p$ and $Q q$ or $P q$ and $Q p$ meet on the curve.
12. A chord $P P^{\prime}$ of a conic meets the directrix in $F$, and from any point $T$ in $P P^{\prime}, T L L^{\prime}$ is drawn parallel to $S F$ and meeting $S P, S P^{\prime}$ in $L$ and $L^{\prime}$; prove that the ratio of $S L$ or $S L^{\prime}$ to the distance of $T$ from the directrix is equal to the ratio of $S A: A X$.
13. If an ellipse and an hyperbola have their axes coincident and proportional, points on them equidistant from one axis have the sum of the squares on their distances from the other axis constant.
14. If $Q$ be any point in the normal $P G, Q R$ the perpendicular on $S P$, and $Q M$ the perpendicular on $P N$,

$$
Q R: P M:: S A: A X
$$

15. The normals at the extremities of a focal chord $P S Q$ of a conic intersect in $K$, and $K L$ is drawn perpendicular to $P Q$; $K F$ is a diagonal of the parallelogram of which $S K, K L$ are adjacent sides: prove that $K F$ is parallel to the transverse axis of the conic.
16. Given a focus of a conic section inscribed in a triangle, find the points where it touches the sides.
17. $P S Q$ is any focal chord of a conic section; the normals at $P$ and $Q$ intersect in $K$, and $K N$ is drawn perpendicular to $P Q$; prove that $P N$ is equal to $S \&$, and hence deduce the locus of $N$.
18. Through the extremity $P$, of the diameter $P Q$ of an ellipse, the tangent $T P T^{\prime \prime}$ is drawn meeting two conjugate diameters in $T, T^{\prime}$. From $P, Q$ the lines $P R, Q R$ are drawn parallel to the same conjugate diameters. Prove that the rectangle under the semiaxes of the ellipse is a mean propurtional between the triangles $P Q R$ and $C T T^{\prime}$.
19. Shew that a conic may be drawn touching the sides of a triangle, having one focus at the centre of the circumscribing circle, and the other at the orthocentre.
20. The perpendicular from the focus of a conic on any tangent, and the central radius to the point of contact, intersect on the directrix.
21. $A B, A C$ are tangents to a conic at $B$, and $C$, and $D E G F$ is drawn from a point $D$ in $A C$, parallel to $A B$ and cutting the curve in $E$ and $F$, and $B C$ in $G$; shew that

$$
D G^{2}=D E . D F .
$$

22. A diameter of a parabola, vertex $F$, meets two tangents in $D$ and $E$ and their chord of contact is $G$, shew that

$$
F G^{2}=E D . F E .
$$

23. If a straight line parallel to an asymptote of an hyperbola meet the curve in $F$ and also meet two tangents in $D$ and $E$ and their chords of contact in $G$;

$$
F G^{2}=F D . F E .
$$

24. $\quad P$ and $Q$ are two fixed points in a parabola, and from any other point $R$ in the curve, $R P, R Q$ are drawn cutting a fixed diameter, vertex $E$, in $B$ and $C$; prove that the ratio of $E B$ to $E C$ is constant.

The same theorem is also true for an hyperbola, if a fixed line parallel to an asymptote be substituted for the diameter of the parabola.
25. If the normal at $P$ meet the transverse axis in $g$, and $g k$ be perpendicular to $S P, P k$ is constant ; and if $k l$ parallel to the transverse axis meet the normal at $P$ in $l, k l$ is constant.
26. A system of conics is drawn having a common focus $S$ and a common latus rectum $L S L^{\prime}$. A fixed straight line through $S$ intersects the conics, and at the points of intersection normals are drawn. Prove that the envelope of each of these normals is a parabola whose focus lies on $L S L^{\prime}$, and which has the given line as tangent at the vertex.

## CHAPTER X.

## HARMONIC PROPERTIES, POLES AND POIAARS.

179. Def. A straight line is harmonically divided in two points when the whole line is to one of the extreme parts as the other extreme part is to the middle part.

Thus $A D$ is harmonically divided in $C$ and $B$, when

$$
A D: A C:: B D: B C
$$

This definition, it will be seen, is the same as that of Art. (17), for $B D=A D-A B$, and $B C=A B-A C$.

Under these circumstances the four points $A, C, B, D$ constitute an Harmonic Range, and if through any point $O$ four straight lines $O A, O C, O B, O D$ be drawn, these four lines constitute an Harmonic Pencil.
180. Prop. I. If a straight line be drawn parallel to one of the rays of an harmonic pencil, its segments made by the other three will be equal, and any straight line is divided harmonically by the four rays.

Let $A C B D$ be the given harmonic range, and draw $E C F$ through $C$ parallel to $O D$, and meeting $O A, O B$ in $\boldsymbol{E}$ and $\boldsymbol{F}$.

Then

$$
\begin{aligned}
& A D: A C:: O D: E C \\
& B D: B C: O D: C F
\end{aligned}
$$

and
but from the definition

$$
\begin{gathered}
A D: A C:: B D: B \dot{C} \\
\therefore E C=C F
\end{gathered}
$$

and any other line parallel to $E C F$ is obviously bisected by $O C$.

Next, let acbd be any straight line cutting the pencil, and draw eff parallel to $O d$; so that $e c=c f$.

Then
and

$$
\begin{aligned}
a d: a c & :: O d: c c \\
b d: b c & : O d: c f ; \\
\therefore a d: a c & :: b d: b c
\end{aligned}
$$

that is, $a c b d$ is harmonically divided.
If the line $c \beta \delta a$ be drawn cutting $A O$ produced,
then
and
or
and similarly it may be shewn in all other cases that the line is harmonically divided.
181. Prop. II. The pencil formed by two straight lines and the bisectors of the angles between them is an harmonic pencil.

For, if $O A, O B$ be the lines, and $O C, O D$ the bisectors, draw $K P L$ parallel to $O C$ and meeting $O A, O D$,
$O B$. Then the angles $O K L$. OLK are obviously equal,

and the angles at $P$ are right angles; therefore $K P=P L$, and the pencil is harmonic.
182. Prop. III. If $A C B D, A c b d$ be harmonic ranges, the straight lines $C c, B b, D d$ will meet in a point, as also $C d, c D, B b$.

For, if $C c, D d$ meet in $F$, join $F b$; then the pencil

$F(A c b d)$ is harmonic, and will be cut harmonically by $A D$.

Hence $F b$ produced will pass through $B$.
Similarly, if $C d, c D$ meet in $E$,
$E(A c b d)$ is harmonic, and therefore $b E$ produced will pass through $B$.

## Harmonic Properties of a Quadrilateral.

In the preceding figure, let $C c d D$ be any quadrilateral; and let $d c, D C$ meet in $A, C d, c D$ in $E$, and $C c$, $D d$ in $F$.

Then taking $b$ and $B$ so as to divide $A c d$ and $A C D$ harmonically, the ranges $A c b d$ and $A C B D$ are harmonic, and therefore $B b$ passes through both $E$ and $F$.

Similarly it can be shewn that $A F$ is divided harmonically in $L$ and $M$, by $D c$ and $d C$.

For $E(A c b d)$ is harmonic and therefore the transversal $A L F M$ is harmonically divided.
183. Prop. IV. If $A C B D$ be an harmonic range, and $E$ the middle point of $C D$,

$$
E A . E B=E C^{2} .
$$

For

$$
A D: A C:: B D: B C
$$

or $A E+E C: A E-E C:: E C+E B: E C-E B$;

$$
\begin{aligned}
& \therefore A E: E C: E C: E B, \\
& A E \cdot E B=E C^{2}=E D^{2} .
\end{aligned}
$$

Hence also, conversely, if $E C^{2}=E D^{2}=A E . E B$, the range $A C B D$ is harmonic, $C$ and $D$ being on opposite sides of $E$.

Hence, if a series of points $A, a, B, b, \ldots$ on a straight line be such that

$$
\begin{aligned}
E A \cdot E a=E B \cdot E b & =E C . E c \ldots \\
& =E P^{2},
\end{aligned}
$$

and if $E Q=E P$, then the several ranges $(A P a Q),(B P b Q)$, $\& c$. are harmonic.
184. Def. A system of pairs of points on a straight line such that

$$
E A \cdot E a=E B \cdot E b=\ldots \quad=E P^{2}=E Q^{2},
$$

is called a system in Involution, the point $E$ being called the centre and $P, Q$ the foci of the system.

Any two corresponding points $A, a$, are called conjugate points, and it appears from above that any two conjugate points form, with the foci of the system, an harmonic range.

It will be noticed that a focus is a point at which conjugate points coincide, and that the existence of a focus is only possible when the points $A$ and $a$ are both on the same side of the centre.
185. Prop. V. Having given two pairs of points $A$ and $a, B$ and $b$, it is required to find the centre and foci of the involution.

If $E$ be the centre,

$$
E A: E B:: E b: E a ;
$$

This determines $E$, and the foci $P$ and $Q$ are given by the relations

$$
E P^{2}=E Q^{2}=E A . E a .
$$

We shall however find the following relation useful.
Since $\quad E A: E b:: E B: E a$;

$$
\begin{aligned}
& \therefore E A: A b:: E B: a B, \\
& E A: E B: A b: a B ;
\end{aligned}
$$

but

| $E b: E A$ | $:: a b: A B ;$ |
| ---: | :--- |
| $\therefore E b: E B$ | $:: A b . b a:: A B . B a$. |
| Again, $\quad Q b: P b$ | $: Q B: P B ;$ |
| $\therefore Q b-P b: P b$ | $:: Q B-P B: P B$, |
| or $2 . E P: P b$ | $:: 2, E B: B P ;$ |
| $\therefore P b^{2}: P B^{2}$ | $:: E P^{2}: E B^{2}$, |
|  | $:: E b: E B$ |
|  | $:: A b . b a: A B . B a$. |

This determines the ratio in which $B b$ is divided by $P$.
186. If $Q A P a$ be an harmonic range and $E$ the middle point of $P Q$, and if a circle be described on $P Q$ as diameter, the lines joining any point $R$ on this circle with $P$ and $Q$ will bisect the angles between $A R$ and $a R$.

For

$$
E A \cdot E a=E P^{2}=E R^{2} ;
$$

$$
\therefore E A: E R:: E R: E a,
$$

and the triangles $A R E, a R E$ are similar.

| Hence | $A R: a R:: E A: E R$ |
| :--- | ---: |
|  | $:: E A: E P$. |
| But | $E a: E P:: E P: E A ;$ |
|  | $\therefore a P: E P:: A P: E A$. |
| Hence | $A R: a R: A P: a P$, |

and $A R a$ is bisected by $R P$.

Hence, if $A$ and $a, B$ and $b$ be conjugate points of a system in involution of which $P$ and $Q$ are the foci, it follows that $A B$ and ab subtend equal angles at any point of the circle on $P Q$ as diameter.

This fact also affords a means of obtaining the relations of Art. 185.

We must observe that if the points $A, a$ are on one side of the centre and $B, b$ on the other, the angles subtended by $A B, a b$ are supplementary to each other.
187. Prop. VI. If four points form an harmonic range, their conjugates also form an harmonic range.

Let $A, B, C, D$ be the four points,
$a, b, c, d$ their conjugates.

|  | $d c b a$ | $A B C D$ |
| :--- | :--- | :--- | :--- |
| $Q$ | $P$ |  |

Then, as in Art. 185,

$$
\begin{gathered}
E a: E D:: a d: A D ; \\
\therefore A D . E a=E D \cdot a d . \\
A C . E a=E C . a c \\
B D \cdot E b=E D . b d, \\
B C . E b=E C \cdot b c .
\end{gathered}
$$

Similarly

But, $A B C D$ being harmonic,

$$
\begin{gathered}
A D: A C:: B D: B C \\
\therefore E D . a d: E C . a c:: E D . b d: E C . \bar{b} c . \\
\quad a d: a c:: b d: b c,
\end{gathered}
$$

Hence
or the range of the conjugates is harmonic.
188. Prop. VII. If a system of conics pass through four given points, any straight line will be cut by the system in a series of points in involution.

The four fixed points being $C, D, E, F$, let the line meet one of the conics in $A$ and $a$, and the straight lines $C F, E D$, in $B$ and $b$.

Then the rectangles $A B . B a, C B . B F$ are in the ratio of the squares on parallel diameters, as also are $A b . b a$ and $D b . b E$.

But the squares on the diameters parallel to $C F, E D$ are in the constant ratio $K F . K C: K E . K D$; and, the line $B b$ being given in position, the rectangles $C B . B F$ and $D b . b E$ are given; therefore the rectangles $A B . B a$, $A b . b a$ are in a constant ratio.

But, Art. 185, this ratio is the same as that of $P B$ $P b^{2}$, if $P$ be a focus of the involution $A, a, B, b$.
Hence $P$ is determined, and all the conics cut the line $B b$ in points which form with $B, b$ a system in involution.

We may observe that the foci are the points of contact of the two conics which can be drawn through the four points touching the line, and that the centre is the intersection of the line with the conic which has one of its asymptotes parallel to the line.
189. Prop. VIII. If through any point two tangents be drawn to a conic, any other straight line through the point will be divided harmonically by the curve and the chord of contact.

Let $A B, A C$ be the tangents, $A D F E$ the straight line.

Through $D$ and $E$ draw GDHK, LEMN parallel to $B C$.

Then the diameter through $A$ bisects $D H$, and $B C$, and therefore bisects $G K$; hence $G D=H K$, and similarly $L E=M N$.

Also

$$
L E: E N:: G D: D K ;
$$

$$
\therefore L E \cdot E N: L E^{2}:: G D \cdot D K: G D^{2},
$$

or $\quad L E \cdot L M: G D . G H:: L E^{2}: G D^{2}$
$:: L A^{2}: G A^{2}$.
But $L E . L M: G D . G H:: L B^{2}: B G^{2}$;
hence $A L: A G:: B L: B G$,

and therefore $\quad A E: A D:: F E: F D$, that is, $A D F E$ is harmonically divided.
190. Prop. IX. If two tangents be drawn to a conic, any third tangent is harmonically divided by the two tangents, the curve, and the chord of contact.

Let $D E F G$ be the third tangent, and through $G$, the
point in which it meets $A C$, draw $G H K L$ parallel to $A B$, cutting the curve and the chord of contact in $H, K, L$.

Then

$$
\begin{aligned}
G H \cdot G L: G C^{2} & : A B^{2}: A C^{2} \\
& :: G K^{2}: G C^{2} ;
\end{aligned}
$$

$\therefore G H . G L=G K^{2}$.
Hence

$$
\begin{aligned}
D G^{2}: D E^{2} & :: G K^{2}: E B^{2} \\
& :: G H \cdot G L: E B^{2} \\
& :: G F^{2}: E F^{2} ;
\end{aligned}
$$

that is, $D E F G$ is an harmonic range.
191. Prop. X. If any straight line meet two tangents to a conic in P and Q, the chord of contact in $T$ and the conic in $R$ and $V$,

$$
P R . P V: Q R . Q V:: P T^{2}: Q T^{2}
$$

Taking the preceding figure, draw the tangent $D E F G$ parallel to $P Q$.

Then
PR.PV:EF $:=P B^{2}: B E^{2}$

$$
:: P T^{2}: D E^{2}
$$

and

$$
Q R \cdot Q V: G F^{2}:: Q C^{2}: G C^{2}
$$

$$
:: Q T^{2}: D G^{2}
$$

but
$E F: D E:: G F: D G ;$
$\therefore P R . P V: P T^{2}: Q R . Q V: Q T^{2}$.
192. Prop. XI. If chords of a conic be drawn through a fixed point the pairs of tangents at their extremities will intersect in a fixed line.

Let $B$ be the fixed point and $C$ the centre, and let $C B$ meet the curve in $P$.

Take $A$ in $C P$ such that

$$
C A: C P:: C P: C B ;
$$

then $B$ is the middle point of the chord of contact of the tangents $A Q, A R$.

Draw any chord $E B F$ and let the tangents at $E$ and $F$ meet in $G$ : also join $C G$ and draw $P N$ parallel to $E F$.

Then if $C G$ meet $E F$ in $K$ and the tangent at $P$ in $T$, $C K . C G=C N . C T ;$
$\therefore C G: C T: O N: C K$
:: $C P$ : $C B$
:: $C A: C P$;
hence $A G$ is parallel to $P T$, and the point $G$ therefore lies on a fixed line.

If the conic be a parabola, we must take $A P$ equal to $B P$ : then, remembering that $K G$ and $N T$ are bisected by the curve, the proof is the same.
193. If $A$ be the fixed point, and if the chord $A E F$ be drawn through $A$, then, as before,

$$
C K . C G=C N . C T,
$$

and

$$
\begin{aligned}
C G: C T & :: C N: C K \\
& :: C P: C A \\
& :: C B: C P ;
\end{aligned}
$$

therefore $B G$ is parallel to $P T$ and coincides with the chord of contact $Q R$.

Hence, conversely, if from points on a straight line pairs of tangents be drawn to a conic, the chords of contact will pass through a fixed point.
194. Def. The locus of the points of intersection of tangents at the extremities of chords through a tixed point is called the polar of the point.

Also, if from points in a straight line pairs of tangents be drawn to a conic, the point in which all the chords of contact intersect is called the pole of the line.

If the pole be without the curve the polar is the chord of contact of tangents from the pole.

If the pole be on the curve, the polar is the tangent at the point.
195. Prop. XII. A straight line drawn through any point is divided harmonically by the point, the curve, and the polar of the point.

If the point be without the conic this is already proved in Art. (189).

If it be within the conic, as $B$ in the figure of Art. (192), then, drawing any chord $F B E V$ meeting in $V$ the polar of $B$, the chord of contact of tangents from $V$ passes through $B$, by Art. (192), and the line $V E B F$ is therefore harmonically divided.

Hence the polar may be constructed by drawing two chords through the pole and dividing them harmonically; the line joining the points of division is the polar.
196. Prop. XIII. The polars of two points intersect in the pole of the line joining the two points.

For, if $A, B$ be the two points and $O$ the pole of $A B$, the line $A O$ is divided harmonically by the curve, and therefore the polar of $A$ passes through the point $O$.

Similarly the polar of $B$ passes through $O$;
That is, the polars of $A$ and $B$ intersect in the pole of $A B$.
197. Prop. XIV. If a quadrilateral be inscribed in a conic, its opposite sides and diagonals will intersect in three points such that each is the pole of the line joining the other two.

Let $A B C D$ be the quadrilateral, $F$ and $G$ the points of intersection of $A D, B C$, and of $D C, A B$.

Let $E G$ meet $F A, F B$, in $L$ and $M$.
Then, Art. (182), FDLA and FCMB are harmonic ranges ;

Therefore $L$ and $M$ are both on the polar of $F$, Art. (195), and $E G$ is the polar of $F$.

Similarly, $E F$ is the polar of $G$, and therefore $E$ is the pole of $F G$; Art. (196).

198. Def. If each of the sides of a triangle be the polar, with regard to a conic, of the opposite angular point, the triangle is said to be self-conjugate with regard to the conic.

Thus the triangle $E G F$ in the above figure is selfconjugate.

To construct a self-conjugate triangle, take a straight line $A B$ and find its pole $C$.

Draw through $C$ any straight line $C D$ cutting $A B$ in $D$, and find the pole $E$ of $C D$, which lies on $A B$ : then $C D E$ is self-conjugate.
199. Prop. XV. If a quadrilateral circumscribe a conic, its three diagonals form a self-conjugate triangle.

Let the polar of $F$ (that is, the chord of contact $P^{\prime} P$ ), meet $F G$ in $R$; then, since $R$ is on the polar of $F$, it follows that $F$ is on the polar of $R$.

Now $F(A E B G)$ is harmonic, Art. (182), and if $F E$ meet $P^{\prime} P$ in $T, P^{\prime} T P R$ is an harmonic range; hence, by the theorem of Art. (195), FE is the polar of $R$.

Similarly, if the other chord of contact $Q Q^{\prime}$ meet $F G$ in $R^{\prime}, G E$ is the polar of $R^{\prime}$;

$\therefore E$ is the pole of $R R^{\prime}$, that is, of $L K$.
Again, $D E B K$ is harmonic, and, if $Q P$ meet $A C$ in $S$ and $C K$ in $V, Q S P V$ is harmonic, and $\therefore S$ is on the polar of $V$; hence, $S$ being on the polar of $C, C V$, that is $C K$, is the polar of $S$.

Similarly, if $P^{\prime} Q^{\prime}$ meet $A C$ in $S^{\prime \prime}, A K$ is the polar of $S^{\prime}$;
$\therefore K$ is the pole of $S S^{\prime}$, that is, of $E L$.
$E L K$ is therefore a self-conjugate triangle.
200. Prop. XVI. If a system of conics have a common self-conjugate triangle, any straight line passing through one of the angular points of the triangle is cut in a series of points in involution.

For, if $A B C$ be the triangle, and a line $A P D Q$ meet $B C$ in $D$, and the conic in $P$ and $Q, A P D Q$ is an harmonic range, and all the pairs of points $P, Q$ form with $A$ and $D$ an harmonic range.

Hence the pairs of points form a system in involution, of which $A$ and $D$ are the foci.
201. Prop. XVII. The pencil formed by the polars of the four points of an harmonic range is an harmonic pencil.

Let $A B C D$ be the range, $O$ the pole of $A D$.
Let the polars $O a, O b, O c, O d$ meet $A D$ in $a, b, c, d$, and let $A D$ meet the conic in $P$ and $Q$.

Then $A P a Q, C P c Q, \& c$. are harmonic ranges; and therefore, Arts. 183, 184, a, c, b, $d$ are the conjugates of $A, C, B, D$.

Hence, Art. (187), the range $a c b d$ is harmonic, and therefore the pencil $O(a c b d)$ is harmonic.

## Reciprocal Polars.

202. The pole of a line with regard to any conic being a point and the polar of a point a line, it follows that any system of points and lines can be transformed into a system of lines and points.

This process is called reciprocation, and it is clear that any theorem relating to the original system will have its analogue in the system formed by reciprocation.

Thus, if a series of lines be concurrent, the corresponding points are collinear; and the theorem of Art. (201) is an instance of the effect of reciprocation.
203. Def. If a point move in a curve ( $C$ ), its polar will always touch some other curve ( $C^{\prime \prime}$ ); this latter curve is called the reciprocal polar of (C) with regard to the auxiliary conic.

Prop. XVII. If a curve $C^{\prime}$ be the polar of $C$, then will $C$ be the polar of $C^{\prime}$.

For, if $P, P^{\prime}$ be two consecutive points of $C$, the intersection of the polars of $P$ and $P^{\prime}$ is a point $Q$, whioh is the pole of the line $P P^{\prime}$.

But the point $Q$ is ultimately, when $P$ and $P^{\prime}$ coin-
cide, the point of contact of the curve which is touched by the polar of $P$.

Hence the polar of any point $Q$ of $C^{\prime}$ is a tangent to the curve $C$.
204. So far we have considered poles and polars generally with regard to any conic; we shall now confine our attention to the simple case in which a circle is the auxiliary curve.

In this case, if $A B$ be a line, $P$ its pole, and $C Y$ the perpendicular from the centre of the circle on $A B$, the rectangle $C P . C Y$ is equal to the square on the radius of the circle.

A simple construction is thus given for the pole of a line, or the polar of the point.
205. As an illustration take the theorem of the existence of the orthocentre in a triangle.

Let $A O D, B O E, C O F$ be the perpendiculars, $O$ being the orthocentre.

The polar reciprocal of the line $B C$ is a point $A^{\prime}$, and of the point $A$ a line $B^{\prime} C^{\prime}$.

To the line $A D$ corresponds a point $P$ on $B^{\prime} C^{\prime}$, and since $A D B$ is a right angle, it follows that $P S A^{\prime}$ is a right angle, $S$ being the centre of the auxiliary circle.

And, similarly, if $S Q, S R$, perpendiculars to $S B^{\prime}, S C^{\prime}$, meet $C^{\prime \prime} A^{\prime}$ and $A^{\prime} B^{\prime}$ in $Q$ and $R$, these points correspond to $B E$ and $C F$.

But $A D, B E, C F$ are concurrent,

$$
\therefore P, Q, R \text { are collinear. }
$$

Hence the reciprocal theorem,
If from any point $S$ lines be drawn perpendicular respectively to $S A^{\prime}, S B^{\prime}, S C^{\prime}$, and meeting $B^{\prime} C^{\prime}, C^{\prime} A^{\prime}$, $A^{\prime} B^{\prime}$ in $P, Q$, and $R$, these points are collinear.

As a second illustration take the theorem,
If $A, B$ be two fixed points, and $A C, B C$ at right angles to each other, the locus of $C$ is a circle.

Taking $O$, the middle point of $A B$, as the centre of
the auxiliary circle, the reciprocals of $A$ and $B$ are two parallel straight lines, $P E, Q F$, perpendicular to $A B$; the reciprocals of $A C, B C$ are points $P, Q$ on these lines such that $P O Q$ is a right angle, and $P Q$ is the reciprocal of $C$.

Hence, the locus of $C$ being a circle, it follows that $P Q$ always touches a circle.

The reciprocal theorem therefore is,
If a straight line $P Q$, bounded by two parallel straight lines, subtend a right angle at a point $O$, halfway between the lines, the line $P Q$ always touches a circle, having $O$ for its centre.
206. Prop. XVIII. The reciprocal polar of a circle with regard to another circle, called the auxiliary circle, is a conic, a focus of which is the centre of the auxiliary circle, and the corresponding directrix the polar of the centre of the reciprocated circle.

Let $S$ be the centre of the auxiliary circle, and $K X$ the polar of $C$, the centre of the reciprocated circle.

Then, if $P$ be the pole of a tangent $Q Y$ to the circle $C, S P$ meeting this tangent in $Y$,

$$
S P . S Y=S X . S C .
$$

Therefore drawing $S L$ parallel to $Q Y$,

$$
S P: S C:: S X: Q L .
$$

But, by similar triangles,

$$
\begin{array}{r}
S P: S C:: S N: C L ; \\
\therefore S P: S C:: N X: C Q, \\
S P: P K: S C: C Q .
\end{array}
$$

or
Hence the locus of $P$ is a conic, focus $S$, directrix $K X$, and having for its eccentricity the ratio of $S C$ to $C Q$.

The reciprocal polar of a circle is therefore an ellipse, parabola, or hyperbola, as the point $S$ is within, upon, or without the circumference of the circle.
207. Prop. XIX. To find the latus rectum and axes of the reciprocal conic.

The ends of the latus rectum are the poles of the tangents parallel to $S C$.

Hence, if $S R$ be the semi-latus rectum,

$$
S R . C Q=S E^{2},
$$

$S E$ being the radius of the auxiliary circle.

The ends of the transverse axis $A, A^{\prime}$ are the poles of the tangents at $F$ and $G$;

$$
\therefore S A \cdot S G=S E^{2}
$$

and

$$
S A^{\prime} . S F=S E^{2}
$$

Let $S U, S U^{\prime}$ be the tangents from $S$, then

$$
S G . S F=S U^{2}
$$

and

$$
\left.\therefore S A^{\prime}: S G:: S E^{2}: S U^{2},\right\}
$$

Hence

$$
A A^{\prime}: F G:: S E^{2}: S U^{2},
$$

or, if $O$ be the centre of the reciprocal,

$$
A O: C Q:: S E^{2}: S U^{2}
$$

Again, if $B O B^{\prime}$ be the conjugate axis,

$$
\begin{gathered}
B O^{2}=S R . A O ; \\
S E^{2}=S R \cdot C Q \\
B O^{2}: S E^{2}:: A O: C Q \\
:: S E^{2}: S U^{2}, \\
B O \cdot S U=S E^{2} .
\end{gathered}
$$

therefore, since
and
The centre $O$, it may be remarked, is the pole of $U U^{\prime}$.
For, from the relations ( $\alpha$ ),

$$
\begin{aligned}
S E^{2}: S U^{2} & :: S A+S A^{\prime}: S F+S G \\
& :: S O: S C \\
& : S O . S M: S C . S M ; \\
\therefore & S O . S M=S E^{2} .
\end{aligned}
$$

208. In the figures drawn, the reciprocal conic is an hyperbola; the asymptotes are therefore the lines through $O$ perpendicular to $S U$ and $S U^{\prime}$, the poles of these lines being at an infinite distance.

The semi-conjugate axis is equal to the perpendicular from the focus on the asymptote, Art. (99), i.e. if $O D$ be the asymptote, $S D$ is equal to the semi-conjugate axis.

Further, since $O D$ is perpendicular to $S U$, and $O$ is the pole of $U U^{\prime}$, it follows that $D$ is the pole of $C U$, and

$$
\therefore S D \cdot S U=S E^{2},
$$

as we have already shewn.
B. c. s.

Again, $D$ being the intersection of the polars of $C$ and $U$, is the intersection of $S U$ and the directrix.
209. If the point $S$ be within the circle, so that the reciprocal is an ellipse, the axes are given by similar relations.

Through $S$ draw $S U$ perpendicular to $F G$.

Then

$$
S F \cdot S G=S U^{2},
$$

and exactly as in the case of the hyperbola,

$$
\begin{gathered}
A O: C Q:: S E^{2}: S U^{2} \\
B O \cdot S U=S E^{2} .
\end{gathered}
$$

and
210. The important Theorem we have just considered enables us to deduce from any property of a circle, a corresponding property of a conic, and we are thus furnished with a method, which may serve to give easy proofs of known properties, or to reveal new properties of conics.

In the process of reciprocation we observe that points become lines and lines points; that a tangent to a curve reciprocates into a point on the reciprocal, that a curve inscribed in a triangle becomes a curve circumscribing a triangle, and that when the auxiliary curve is a circle, the reciprocal of a circle is a conic, the latus rectum of which varies inversely as the radius of the circle.
211. We give a few instances :

## Theorem.

The angles in the same seg. ment of a circle are equal.

Two of the common tangents of two equal circles are parallel.

If a chord of a circle subtend a constant angle at a fixed point on the curve, the chord always touches a circle.

If a chord of a circle pass through a fixed point, the rectangle contained by the segments is constant.

If two chcrds be drawn from a fixed point on a circle at right angles to each other, the line joining theirends passes through the centre.

If a circle be inscribed in a triangle, the lines joining the vertices with the points of contact meet in a point.

The sum of the reciprocals of the radii of the escribed circles of a triangle is equal to the reciprocal of the inscribed circle.

Reciprocal.
If a moveable tangent of a conic meet two fixed tangents, the intercepted portion subtends a constant angle at the fucus.

If two conics have the same focus, and equal latera recta, the straight line joining two of their common points passes through the focus.

If two tangents of a conic move so that the intercepted portion of a fixed tangent subtends a constant angle at the focus, the locus of the intersection of the moving tangents is a conic having the same focus and directrix.

The rectangle contained by the perpendiculars from the focus on two parallel tangents is constant.

If two tangents of a conic move so that the intercepted portion of a fixed tangent subtends a right angle at the focus, the two moveable tangents meet in the directrix.

If a triangle be inscribed in a conic the tangents at the vertices meet the opposite sides in three points lying in a straight line.

With a given point as focus, four conics can be drawn circumscribing a triangle, and the latus rectum of one is equal to the sum of the latera recta of the other three.

## EXAMPLES.

1. If a series of circles pass through the same two points, any transversal will be cut by the circles in a series of points in involution.
2. If $O$ be the centre of the circle circumscribing a triangle $A B C$, and $B^{\prime} C^{\top}, C^{\prime} A^{\prime}, A^{\prime} B^{\prime}$, the respective polars with regard to a concentric circle of the points $A, B, C$, prove that $O$ is the centre of the circle inscribed in the triangle $A^{\prime} B^{\prime} C^{\prime}$.
3. $O A, O B, O C$ being three straight lines given in position, shew that there are three other straight lines each of which forms with $O A, O B, O C$ an harmonic pencil; and that each of the three $O A, O B, O C$ forms with the second three an harmonic pencil.
4. The straight line $A B C D$ is divided harmonically in the points $B, C$; prove that if a circle be described on $A C$ as diameter, any circle passing through $B$ and $D$ will cut it at right angles.
5. Three straight lines $A D, A E, A F$ are drawn through a fixed point $A$, and fixed points $B, C, D$ are taken in $A D$, such that $A B C D$ is an harmonic range. Any straight line through $C$ intersects $A E$ and $A F$ in $E$ and $F$, and $B E, D F$ intersect in $P ; D E, B F$ in $Q$. Shew that $P$ and $Q$ always lie in a straight line through $A$, forming with $A D, A E, A F$ an harmonic pencil.
6. $C A, C B$ are two tangents to a conic section, $O$ a fixed point in $A B, P O Q$ any chord of the conic ; prove that the intersections of $A P, B Q$, and also of $A Q, B P$ lie in a fixed straight line which forms with $C A, C O, C B$ an harmonic pencil.
7. If three conics pass through the same four points, the common tangent to two of them is divided harmonically by the third.
8. Two conics intersect in four points, and through the intersection of two of their common chords a tangent is drawn to one of them; prove that it is divided harmonically by the other.
9. Prove that the two tangents through any point to a conic, any line through the point and the line to the pole of the last line, form an harmonic pencil.
10. Shew that the asymptotes of an hyperbola form, with any pair of conjugate diameters, an harmonic pencil.
11. Shew, from Arts. 195 and 196, that the centre of a conic is the pole of a line at an infinite distance.
12. $P S Q$ and $P S^{\prime} R$ are two focal chords of an ellipse; two other ellipses are described having $P$ for a common focus, and touching the first ellipse at $Q$ and $R$ respectively. The three ellipses have equal major axes. Prove that the directrices of the last two ellipses pass through the pole of $Q R$.
13. Tangents from $T$ touch an ellipse in $P$ and $Q$, and $P Q$ meets the directrices in $R$ and $R^{\prime}$; shew that $P R$ and $Q R^{\prime}$ subtend equal angles at $T$.
14. The poles of a given straight line, with respect to sections through it of a given cone, all lie upon a straight line passing through the vertex of the cone.
15. If from a given point in the axis of a conic a chord be drawn, the perpendicular from the pole of the chord upon the chord will meet the axis in a fixed point.
16. $Q$ is any point in the tangent at a point $P$ of a conic ; $Q G$ perpendicular to $C P$ meets the normal at $P$ in $G$, and $Q E$ perpendicular to the polar of $Q$ meets the normal at $P$ in $E$; prove that $E G$ is constant and equal to the radius of curvature at $P$.
17. If any triangle be reciprocated with regard to its orthocentre, the reciprocal triangle will be similar and similarly situated to the original one and will have the same orthocentre.
18. If two conics have the same focus and directrix, and a focal chord be drawn, the four tangents at the points where it meets the conics intersect in the same point of the directrix.
19. An ellipse and a parabola have a common focus; prove that the ellipse either intersects the parabola in two points and has two common tangents with it, or else does not cut it.
20. Prove that the reciprocal polar of the circumscribed circle of a triangle with regard to the inscribed circle is an ellipse, the major axis of which is equal in length to the radius of the inscribed circle.
21. Prove that fuur parabolas, having a common focus, may be described so that each shall touch three out of four given straight lines.
22. A triangle $A B C$ circumscribes a parabola, focus $S$; through $A B C$ lines are drawn respectively perpendicular to $S A$, $S B, S C$; shew that these lines meet in a point.
23. A tangent to an ellipse at a point $P$ intersects a fixed tangent in $T$; if through a focus $S$ a line be drawn perpendicular to $S T$, meeting the tangent at $P$ in $Q$, the locus of $Q$ is a straight line touching the ellipse.
24. Prove that the distances, from the centre of a circle, of any two poles are to one another as their distances from the alternate polars.
25. If $P, Q, R$ be three points on a conic, and $P R, Q R$ meet the directrix in $p, q$, the angle which $p q$ subtends at the corresponding focus is half the angle which $P Q$ subtends.
26. Reciprocate the theorems,
(1) The opposite angles of any quadrilateral insoribed in a circle are equal to two right angles.
(2) If a line be drawn from the focus of an ellipse making a constant angle with the tangent, the locus of its intersection with the tangent is a circle.
27. The locus of the intersection of two tangents to a parabola which include a constant angle is an hyperbola, having the same focus and directrix.
28. Two ellipses having a common focus cannot intersect in more than two real points, but two hyperbolas, or an ellipse and hyperbola, may do so.
29. $A B C$ is any triangle and $P$ any point: four conic sections are described with a given focus touching the sides of the triangles $A B C, P B C, P C A, P A B$ respectively, shew that they all have a common tangent.
30. $T P, T Q$ are tangents to a parabola cutting the directrix respectively in $X$ and $Y ; E S F$ is a straight line drawn through the focus $S$ perpendicular to $S T$, cutting $T P, T Q$ respectively in $E, F$; prove that the lines $E Y, X F$ are tangents to the parabola.
31. With the orthocentre of a triangle as focus, two conics are described touching a side of the triangle and having the other two sides as directrices respectively; shew that their minor axes are equal.
32. Conics have a focus and a pair of tangents common ; the corresponding directrices will pass through a fixed point, and all the centres lie on the same straight line.
33. The focal distances of a point on a conic meet the curve again in $Q, R$; shew that the pole of $Q R$ will lie upon the normal at the first point.
34. The tangent at any point $A$ of a conic is cut by two other tangents and their chord of contact in $B, C, D$; shew that $(A B D C)$ is harmonic.
35. $P Q$ is the chord of a conic having its pole on the chord $A B$, (or $A B$ produced); $Q q$ is drawn parallel to $A B$ meeting the conic in $q$; shew that $P q$ bisects the chord $A B$.
36. Prove that with a given point as focus, four conics can be drawn circumscribing a given triangle, and that the sum of the latera recta of three of them will equal the latus rectum of the fourth.

If the sides of the triangle subtend equal angles at the given point one of the conics will touch the other three.
37. Two parabolas have a common focus $S$; parallel tangents are drawn to them at $P$ and $Q$ intersecting the common tangent in $P^{\prime}$ and $Q^{\prime}$; prove that the angle $P S Q$ is equal to the angle between the axes, and the angle $P^{\prime} S Q^{\prime}$ is supplementary.

Deduce the reciprocal Theorem for two circles.
38. Two circles can be reciprocated into a pair of confocal conics.
39. A system of coaxal circles can be reciprocated into a system of confocal conics.
40. $A B C$ is a given triangle, $S$ a given point ; on $B C, C A$, $A B$ respectively, points $A^{\prime}, B^{\prime}, C^{\prime}$ are taken, such that each of the angles $A S A^{\prime}, B S B^{\prime}, C S C^{\prime}$, is a right angle. Prove that $A^{\prime}, B^{\prime}, C^{\prime}$ lie in the same straight line, and that the latera recta of the four conics, which have $S$ for a common focus, and respectively touch the three sides of the triangles $A B C, A B^{\prime} C^{\prime}$, $A^{\prime} B C^{\prime}, A^{\prime} B^{\prime} C$ are equal to one another.
41. $S$ is the focus of a conic; $P, Q$ two points on it such that the angle $P S Q$ is constant; through $S, S R, S T$ are drawn meeting the tangents at $P, Q$ in $R, T$ respectively, and so that the angles $P S R, Q S T$ are constant; shew that $R T$ always touches a conic having the same focus and directrix as the original conic.
42. $O A, O B$ are common tangents to two conics having a common focus $S, C A, C B$ are tangents at one of their points of intersection, $B D, A E$ tangents intersecting $C A, C B$, in $D, E$. Prove that $S D E$ is a straight line.
43. An hyperbola, of which $S$ is one focus, touches the sides of a triangle $A B C$; the lines $S A, S B, S C$ are drawn, and also lines $S D, S E, S F$ respectively perpendicular to the former three lines, and meeting any tangent to the curve in $D, E, F$; shew that the lines $A D, B E, C F$ are concurrent.
44. A rectangular hyperbola circumscribes a triangle $A B C$; if $D, E, F$ be the feet of the perpendiculars from $A, B, C$ on the opposite sides, the loci of the poles of the sides of the triangle $A B C$ are the lines $E F, F D, D E$.
45. Two common chords of a given ellipse and a circle pass through a given point; shew that the locus of the centres of all such circles is a straight line through the given point.
46. If an hyperbola circumscribe an equilateral triangle, and have the centre of the circumscribing circle as focus, its ecceutricity is the ratio of 4 to 3 , and its latus rectum is one-third of the diameter of the circumscribing circle.
47. If a triangle is self-conjugate with respect to each of a series of parabolas, the lines joining the middle points of its sides will be tangents; all the directrices will pass through 0 , the centre of the circumscribing circle; and the focal chords, which are the polars of 0 , will all touch an ellipse inscribed in the given triangle which has the nine-point circle for its auxiliary circle.

## CHAPTER XI.

## THE CONSTRUCTION OF A CONIC FROM GIVEN CONDITIONS.

212. It will be found that, in general, five conditions are sufficient to determine a conic, but it sometimes happens that two or more conics can be constructed which will satisfy the given conditions. We may have, as given conditions, points and tangents of the curve, the directions of axes or conjugate diameters, the position of the centre, or any characteristic or especial property of the curve.

Prop. I. To construct a parabola, passing through three given points, and having the direction of its axis given.

In this case the fact that the conic is a parabola is one of the conditions.

Let $P, Q, R$ be the given points, and let $R E$ parallel to the given direction meet $P Q$ in $E$.

If $E$ be the middle point of $P Q, R$ is the vertex of the diameter $R E$; but, if not, bisecting $P Q$ in $V$, draw the diameter through $V$ and take $A$ such that

$$
A V: R E:: Q V^{2}: Q E \cdot E P .
$$

Then $A$ is the vertex of the diameter $A V$.
If the point $E$ do not fall between $P$ and $Q, A$ must be taken on the side of $P Q$ which is opposite to $R$.

The focus may then be found by taking $A U$ such that

$$
Q V^{2}=4 A V . A U
$$

and by then drawing $U S$ parallel to $Q V$ and taking $A S$ equal to $A U$.
213. Prop. II. To describe a parabola through four. given points.

First, let $A B C D$ be four points in a given parabola, and let the diameter $C F$ meet $A D$ in $F$.

Draw the tangents $P T, Q T$ parallel to $A D, B C$, and the diameter $Q V$ meeting $P T$ in $V$.

Then ED.EA : EC.EB :: $T P^{2}: T Q^{2}$

$$
\begin{aligned}
& :: T V^{2}: T Q^{2} \\
& :: E F^{2}: E C^{2}
\end{aligned}
$$

Hence the construction ; in $E A$ take $E F$ such that

$$
E F^{2}: E C^{2}:: E D . E A: E C \cdot E B,
$$

then $C F$ is the direction of the axis, and the problem is reduced to the preoeding.

If the point $F$ be taken in $A E$ produced, another parabola can be drawn, so that, in general, two parabolas can be drawn through four points.
214. This problem may be treated differently by help of the theorem of Art. (48), viz.;

Iffrom a point $O$, outside a parabola, a tangent $O M$, and $a$ chord $O A B$ be drawn, and if the diameter $M E$ meet the chord in $E$,

$$
O E^{2}=O A . O B
$$

Let $A, B, C, D$ be the given points, and let $E, E^{\prime}$, $F, F^{\prime}$, be so taken that
and

$$
O E^{2}=O E^{\prime 2}=O A \cdot O B
$$

Then $E F$ and $E^{\prime} F^{\prime}$ are diameters, and $K L$, the polar of $O$, will meet $E F$ and $E^{\prime} F^{\prime}$ in $M, N$, the points of contact of tangents from 0 .

The second parabola is obtained by taking for diameters $E F^{\prime}$ and $E^{\prime} F^{\prime}$.
215. Prop. III. Any conic passing through four points has a pair of conjugate diameters parallel to the axes of the two parabolas which can be drawn through the four points.

Let $T P, T Q$ be the tangents parallel to $O A B$ and $O C D$, and such that the angle $P T Q$ is equal to $A O C$.

Then, if $O E^{2}=O A . O B$ and $O F^{2}=O C . O D$,

$$
\begin{aligned}
O E^{2}: O F^{2} & :: O A . O B: O C . O D \\
& :: T P^{2}: T Q^{2} ;
\end{aligned}
$$

$\therefore E F$ is parallel to $P Q$.
Hence, if $R$ and $V$ be the middle points of $E F$ and $P Q$, $O R$ is parallel to $T V$;

But taking $O F^{\prime \prime}$ equal to $O F, O R$ is parallel to $E F^{\prime}$,
$\therefore T V$ and $P Q$ are parallel to $E F^{\prime}$ and $E F$;
i.e. the conjugate diameters parallel to $T V$ and $P Q$ are parallel to the axes of the two parabolas.
216. Prop. IV. Having given a pair of conjugate diameters, $P C P^{\prime}, D C D^{\prime}$, it is required to construct the ellipse.

In $C P$ take $E$ such that $P E . P C=C D^{2}$, draw $P F$ perpendicular to $C D$ and take $F C^{\prime}$ equal to $F C$.

About $C E C^{\prime \prime}$ describe a circle, cutting $P F$ in $G$ and $G^{\prime}$; then

$$
P G . P G^{\prime}=P E \cdot P C=C D^{2},
$$

and $G C G^{\prime}$ is a right angle; therefore $C G$ and $C G^{\prime}$ are the directions of the axes and their lengths are given by the relations,

$$
\begin{aligned}
& P G . P F=B C^{2} \\
& P G^{\prime} . P F=A C^{2} .
\end{aligned}
$$

We may observe that, $O$ being the centre of the circle,

$$
\begin{aligned}
A C^{2}+B C^{2} & =P F \cdot P G+P F \cdot P G^{\prime} \\
& =2 \cdot P F \cdot P O \\
& =2 \cdot P C \cdot P N,
\end{aligned}
$$

if $N$ be the middle point of $C E$,

$$
\begin{aligned}
& =P C^{2}+P C \cdot P E \\
& =C P^{2}+C D .
\end{aligned}
$$

If $P E^{\prime}$ be taken equal to $P E$ in $C P$ produced, and the same construction be made, we shall obtain the axes of an hyperbola having $C P, C D$ for a pair of conjugate semidiameters.
217. This problem may be treated also as follows.

In $P F$, the perpendicular on $C D$, take

$$
P K=P K^{\prime}=C D
$$

then

$$
P K^{2}=P G \cdot P G^{\prime},
$$

and therefore $K^{\prime} G K G^{\prime}$ is an harmonic range; and $G C G^{\prime}$ being a right angle, it follows, Art. 181, that $C G$ and $C G^{\prime}$ are the bisectors of the angles between $C K$ and $C K^{\prime}$.

Hence, knowing $C P$ and $C D, G$ and $G^{\prime}$ are determined.
218. Prop. V. Having given the focus and three points of a conic, to find the directrix.

Let $A, B, C, S$ be the three points and the focus.
Produce $B A$ to $D$ so that

$$
B D: A D:: S B: S A
$$

and $C B$ to $E$, so that

$$
B E: C E:: S B: S C ;
$$

then $D E$ is the directrix.
The lines $B A, B C$ may be also divided internally in the same ratio, so that four solutions are generally possible.

Conversely, if three points $A, B, C$ and the directrix are given, let $B A, B C$ meet the directrix in $D$ and $E$; then $S$ lies on a circle, the locus of a point, the distances of which from $A$ and $B$ are in the ratio of $A D$ to $D B$.
$S$ lies also on a circle, similarly constructed with regard to $B C E$; the intersection of these circles gives two points, either of which may be the focus.
219. Prop. VI. Having given the centre, the directions of a pair of conjugate diameters, and two points of an ellipse, to describe the ellipse.

If $C$ be the centre, $C A, C B$ the given directions, and

$P, Q$ the points, draw $Q M Q^{\prime}, P L P^{\prime}$ parallel to $C B$ and $C A$, and make $Q^{\prime} M=Q M$ and $P^{\prime} L=P L$.

Then the ellipse will evidently pass through $P^{\prime}$ and $Q^{\prime}$, and if $C A, C B$ be the conjugate radii, their ratio is given by the relation

$$
C A^{2}: C B^{2}:: E P \cdot E P^{\prime}: E Q . E Q^{\prime}
$$

$E$ being the point of intersection of $P^{\prime} P$ and $Q^{\prime} Q$.
Set up a straight line $N D$ perpendicular to $C A$ and such that

$$
N D^{2}: N P^{2}:: E P \cdot E P^{\prime}: E Q . E Q^{\prime},
$$

and describe a circle, radius $C D$ and centre $C$ cutting $C A$ in $A$, and take

Then

$$
C B: C A:: N P: N D .
$$

$$
A N . N A^{\prime}=N D^{2}
$$

and

$$
P N^{2}: A N . N A^{\prime}: C B^{2}: C A^{2}
$$

Hence $C A, C B$ are determined, and the ellipse passes through $P$ and $Q$.
220. Prop. VII. To describe a conic passing through a given point and touching two given straight lines in given points.

Let $O A, O B$ be the given tangents, $A$ and $B$ the points of contact, $N$ the middle point of $A B$.

1st. Let the given point $D$ be in $O N$; then, if $N D=O D$, the curve is a parabola.

But if $N D<O D$, the curve is an ellipse, and, taking $C$ such that $O C . C N=C D^{2}$, the point $C$ is the centre.

If $N D>O D$ the curve is an hyperbola, and its centre is found in the same manner.

2nd. If the given point be $E$, not in $O N$, draw $G E F$, parallel to $A B$, and make $F L$ equal to $E L$.

Take $K$ such that

$$
G K^{2}=G E . G F,
$$

then $A K$ produced will meet $O N$ in $D$, and the problem is reduced to the first case.

To justify this construction, observe that if $D M$ be the tangent at $D$,

$$
\begin{aligned}
& G E \cdot G F: G A^{2} \\
&:: D M^{2}: M A^{2} \\
&:: G K^{2}: G A^{2},
\end{aligned}
$$

so that

$$
G E . G F=G K^{2} .
$$

221. Prop. VIII. To draw a conic through five given points.

Let $A, B, C, D, E$ be the five points, and $F$ the intersection of $D E, A B$.

Draw $C G, C H$, parallel respectively to $A B$ and $E D$ and meeting $E D, A B$ in $G$ and $H$.

If $F$ and $G$ fall between $D$ and $E$, and $F$ and $H$ between $A$ and $B$, take $G P$ in $C G$ produced and $H Q$ in $C H$ produced, such that

$$
C G \cdot G P: D G \cdot G E:: A F \cdot F B: D F \cdot F E,
$$

and $C H . H Q: A H . H B: D F \cdot F E: A F \cdot F B$;
Then, Arts. (86) and (129), $P$ and $Q$ are points in the conic.

Also $P C, A B$ being parallel chords, the line joining their middle points is a diameter, and another diameter is obtained from $C Q$ and $D E$.

If these diameters are parallel, the conic is a parabola, and we fall upon the case of Prop. II.; but if they intersect in a point $O$, this point is the centre of the conic, and, having the centre, the direction of a diameter, and

[^1]two ordinates of that diameter, we fall upon the case of Prop. VI.

The figure is drawn for the case in which the pentagon $A E B C D$ is not re-entering, in which case the conic may be an ellipse, a parabola, or an hyperbola.

If any one point fall within the quadrilateral formed by the other four, the curve is an hyperbola.

In all cases the points $P, Q$ must be taken in accordance with the following rule.

The points $C, P$, or $C, Q$ must be on the same or different sides of the points $G$, or $H$, according as the points $D, E$, or $B, A$ are on the same or different sides of the points $G$ or $H$.

Thus, if the point $E$ be between $D$ and $F$, and if $G$ be between $D$ and $E$, and $H$ between $A$ and $B$, the points $P$ and $O$ will be on the same side of $G$, and $C, Q$ on the same side of $H$, but if $H$ fall outside $A$ and $B, C$ and $Q$ will be on opposite sides of $H$.

Remembering that if a straight line meet only one branch of an hyperbola, any parallel line will meet only. one branch, and that if it meet both branches, any parallel will meet both branches, the rule may be established by an examination of the different cases.
222. The above construction depends only on the elementary properties of Conics, which are given in Chapters I, II, III, and IV. For some further constructions we shall adopt another method depending on harmonic properties.

Prop. IX. Having given two pairs of lines $O A, O A^{\prime}$, and $O B, O B^{\prime}$, to find a pair of lines $O C, O C^{\prime}$, which shall make with each of the given pairs an harmonic pencil.

This is at once effected by help of Art. (185).
For, if any transversal cut the lines in the points $c, a, b$, $c^{\prime}, b^{\prime}, a^{\prime}$, the points $c, c^{\prime}$ are the foci of the involution, in which $a, a^{\prime}$ are conjugate, and also $b, b^{\prime}$, the centre of the involution being the middle point of $c c^{\prime}$.
223. Prop. X. If two points and two tangents of a conic be given, the chord of contact intersects the given chord in one of two fixed points*.

Let $O P, O Q$ be the given tangents, $A$ and $B$ the giveu

points, and $C$ the intersection of $A B$ and the chord of contact.

Let $O C^{\prime}$ be the polar of $C$, and let $A B$ meet $O C^{\prime}$ in $D$,
Then $C$ is on the polar of $D$, and therefore $D B C A$ is an harmonic range.

- Also, $C$ being on the polar of $C^{\prime}, C^{\prime} Q C P$ is an harmonic range.

Hence if two lines $O C, O C^{\prime}$ be found, which are harmonic with $O A, O B$, and also with $O P, O Q$, these lines intersect $A B$ in two points $C$ and $D$, through one of which the chord of contact must pass.

Or thus, if the tangents meet $A B$ in $a$ and $b$, find the foci $C$ and $D$ of the involution $A B, a b$; the chord of contact passes through one of these points.

* I am indebted to Mr Worthington for much valuable assistance in this chapter, and especially for the constructions of Articles 223, 225, 226, and 229.

224. Prop. XI. Having given three points and two tangents, to find the chord of contact.

In the preceding figure let $O P, O Q$ be the tangents, and $A, B, E$ the points.

Find $O C, O C^{\prime}$ harmonic with $O A, O B$, and $O P, O Q$; also find $O F, O G$ harmonic with $O A, O E$ and $O P, O Q$.

Then any one of the four lines joining $C$ or $D$ to $F$ or $G$ is a chord of contact, and the chord of contact and points of contact being known, the case reduces to that of Art. (220).

Hence four such conics can in general be described.
225. Prop. XII. To describe a conic, passing through two given points, and touching three given straight lines.

Let $A B$, the line joining the given points, meet the given tangents $Q R, R P, P Q$, in $N, M, L$.

Find the foci $C, D$ of the involution $A, B$ and $L, M$;
Then $Y Z$, the polar of $P$, passes through $C$ or $D$. Art. 223.

Also find the foci, $F, G$, of the involution $A, B$, and $M, N$; then $X Y$, the polar of $R$, passes through $F$ or $G$.

Let $Z X$ meet $P R$ in $T$; then $T$ is on the polar of $Q$, and $Q Y$ is the polar of $T$.

Hence $T X U Z$ is harmonic ;

This determines $V$, and joining $Q V$, we obtain the point of contact $Y$.

Then, joining $Y C$ and $Y F, Z$ and $X$ are obtained, and $X, Y, Z$ being points of contact, we have five points, and can describe the conic by the construction of Art. (221), or by that of Art. (228).

Since either $C$ or $D$ may be taken with $F$ or $G$, there are in general four solutions of the problem.
226. Prop. XIII. To describe a conic, having given four points and one tangent.

Let $A, B, C, D$ be the given points, and complete the quadrilateral.

Then $E$ is the pole of $F G$, and if the given tangent $K L$ meet $F G$ in $K, E$ is on the polar of $K$; therefore the other tangent through $K$ forms an harmonic pencil with $K F$, $K L, K E$.

Hence two tangents being known, and a point $E$ in the chord of contact, if we find two points $P, P^{\prime}$ in $A, B$, such that $K P, K P^{\prime}$ are harmonic with $K A, K B$, and also with $K L, K L^{\prime}$, we shall have two chords of contact $E P, E P^{\prime}$, and therefore two points of contact for $K L$ and also for $K L^{\prime}$.

Hence two conics can be described.
We observe that if two conics pass through four points, their common tangents meet on one of the sides of the selfconjugate triangle EFG.
227. Prop. XIV. Given four tangents and one point, to construct the conic.

Let $A B C D$ be the given circumscribing quadrilateral, and $E$ the given point. Completing the figure, draw $L E F^{\prime}$

through $E$ and $F$, and complete the harmonic range $L E F E^{\prime}$; then, since $F$ is the pole of $H G$, Art. (197), $E^{\prime}$ is a point in the conic.

Also since $K$ is the pole of $F A$, Art. 199, the chord of contact of the tangents $A B, A D$, passes through $K$.

Hence the construction is the same as that of Art. 226, and there are two solutions of the problem.
228. Prop. XV. Given five points, to construct the conic.

Let $A, B, C, D, E$ be the five points, and complete the quadrilateral $A B C D$.

Then $H$ is the pole of $F G$, and $F G$ passes through the points of contact $P, Q$ of the tangents from $H$.

Join $H E$, cutting $F G$ in $K$, and complete the harmonic range $H E K E^{\prime}$; then $E^{\prime}$ is a point in the conic.

Also $A E, B E^{\prime}$ will intersect $F G$ in the same point $F^{\prime}$, and $E^{\prime} A, E B$ will also intersect $F G$ in the same point $G^{\prime}$.

But $G P F Q$ and $G^{\prime} P F^{\prime} Q$ are both harmonic ranges, therefore $P$ and $Q$ are the foci of an involution of which $F, G$ and $F^{\prime}, G^{\prime}$ are pairs of conjugate points.

Hence, finding these foci, $P$ and $Q$, the tangents $H P$, $H Q$ are known, and the case is reduced to that of Prop. VII.

Hence only one conic can be drawn through five points.
229. Prop. XVI. Given five tangents, to find the points of contact.

Let $A B C D E$ be the circumscribing pentagon. Con-

sidering the quadrilateral $F B C D$, join $F C, B D$ meeting in $K$.
232. The Construction of a Conic, \&c.

Then, (Art. 199), $K$ is the pole of the line joining the intersections of $F B, C D$, and of $F D, B C$; that is, the chords of contact of $B F, C D$, and of $B C, F D$ meet in $K$.

Similarly if $B G, A C$ meet in $L$, the chords of contact of $A B, C G$, and of $B C, A G$ meet in $L$.

Hense $K L$ is the chord of contact of $A B, C D$, and therefore determines $M, N$ the points of contact.

Hence it will be seen that only one conic can be drawn touching five lines.

## CHAPTER XII.

## THE OBLIQUE CYLINDER, THE OBLIQUE CONE, AND THE CONOIDS.

230. Def. If a straight line, which is not perpendicular to the plane of a given circle, move parallel to itself, and always pass through the circumference of the circle, the surface generated is called an oblique cylinder.

The line through the centre of the circular base, parallel to the generating lines, is the axis of the cylinder.

It is evident that any section by a plane parallel to the axis consists of two parallel lines, and that any section by a plane parallel to the base is a circle.

The plane through the axis perpendicular to the base is the principal section.

The section of the cylinder by a plane perpendicular to the principal section, and inclined to the axis at the same angle as the base, is called a subcontrary section.
231. Prop. I. The subcontrary section of an oblique cylinder is a circle.

The plane of the paper being the principal plane and $A P B$ the circular base, a subcontrary section is $D P E$, the angles $B A E, D E A$ being equal.

Let $P Q$ be the line of intersection of the two circles;
then

$$
P N . N Q \text { or } P N^{2}=B N . N A .
$$

234 The Oblique Cylinder, the Oblique Cone,
But

$$
N B=N D, \text { and } N A=N E ;
$$

$\therefore P N . N Q=D N . N E$,
and $D P E$ is a circle.
232. Prop. II. The section of an oblique cylinder by a plane which is not parallel to the base or to a subcontrary section is an ellipse.

Let the plane of the section, $D P E$, meet any circular section in the line $P Q$, and let $A B$ be that diameter of the

circular section which is perpendicular to $P Q$, and bisect $P Q$ in the point $F$.

Let the plane through the axis and the line $A B$ cut the section $D P E$ in the line $D F E$.

Then

$$
P F^{2}=A F . F B
$$

But if $D E$ be bisected in $C$, and $G K C$ bo the circular section through $C$ parallel to $A P B$,
and

$$
\begin{aligned}
& A F: F D:: C G: C D, \\
& F B: F E:: C G: C D
\end{aligned}
$$

$$
\therefore A F \cdot F B: D F \cdot F E:: C G^{2}: C D^{2} ;
$$

hence, observing that $C G=C K$,

$$
P F^{2}: D F \cdot F E:: C K^{2}: C D^{2} .
$$

But, if a series of parallel circular sections be drawn, $P Q$ is always parallel to itself and bisected by $D E$;

Therefore the curve $D P E$ is an ellipse, of which $C D$, $C K$ are conjugate semi-diameters.
233. Def. If a straight line pass always through a fixed point and the circumference of a fixed circle, and if the fixed point be not in the straight line through the centre of the circle at right angles to its plane, the surface generated is called an oblique cone.

The plane containing the vertex and the centre of the base, and also perpendicular to the base, is called the principal section.

The section made by a plane not parallel to the base, but perpendicular to the principal section, and inclined to

236 The Oblique Cylinder, the Oblique Cone, the generating lines in that section at the same angles as the base, is called a subcontrary section.
234. Prop. III. The subcontrary section of an oblique cone is a circle.

The plane of the paper being the principal section, let

$A P B$ be parallel to the base and $D P E$ a subcontrary section, so that the angle
and

$$
O D E=O A B
$$

$O E D=O B A$.
The angles $D B A, D E A$ being equal to each other, a circle can be drawn through $B D A E$.

Hence, if $P N Q$ be the line of intersection of the two planes,

$$
\begin{aligned}
D N \cdot N E & =B N \cdot N A \\
& =P N \cdot N Q
\end{aligned}
$$

therefore $D P E$ is a circle.
And all sections by planes parallel to $D P E$ are circles.
Planes parallel to the base, or to a subcontrary section, are called also Cyclic Planes.
235. Prop. IV. The section of a cone by a plane not parallel to a cyclic plane is an Ellipse, Parabola, or Hyperbola.
(1) Let the section, $D P E$, meet all the generating lines on one side of the vertex.

Let any circular section cut $D P E$ in $P Q$, and take $A B$ the diameter of the circle which is at right angles to, and bisects $P Q$.

The plane $O A B$ will cut the plane of the section in a line $D N E$.

Draw $O K$ parallel to $D E$ and meeting in $K$ the plane of the circular section through $D$ parallel to $A P B$, and join $D K$, meeting $O E$ in $F$.

```
Then
\[
A N: N D:: K D: O K
\]
\[
B N: N E:: K F: O K
\]
\[
\text { therefore } A N . N B: D N . N E:: K D \cdot K F: O K^{2},
\]
or
\[
P N^{2}: D N . N E:: K D . K F: O K^{2} .
\]
```

But if a series of circular sections be drawn the lines $P Q$ will always be parallel, and bisected by $D E$;

238 The Oblique Cylinder, the Oblique Cone,
Therefore the curve $D P E$ is an eilipse, having $D E$ for a diameter, and the conjugate diameter parallel to $P Q$, and the squares on these diameters are in the ratio of $K D . K F$ to $O K^{2}$.
(2) Let the section be parallel to a tangent plane of the cone.

If $O B$ be the generating line along which the tangent plane touches the cone, and $B T$ the tangent line at $B$ to a

circular section through $B$, the line of intersection $P Q$ will be parallel to $B T$, and therefore perpendicular to the diameter $B A$ through $B$.

Let the plane $B O A$ cut the plane of the section in $D N$.
Then drawing $D K$ parallel to $A B$,

$$
\begin{gathered}
B N=K D \\
A N: N D:: K D: O K
\end{gathered}
$$

and
therefore $A N . N B: N D . K D:: K D: O K$,
or

$$
P N^{2}: N D . K D:: K D: O K
$$

and $K D, O K$ being constant, the curve is a parabola having the tangent at $D$ parallel to $P Q$.

If the plane of the section meet both branches of the

cone, make the same construction as before, and we shall obtain, in the same manner as for the ellipse,

$$
P N^{2}: D N . N E:: D K . K F: O K^{2},
$$

$O \bar{K}$ being parallel to $D E$.
Therefore, since the point $N$ is not between the points $D$ and $E$, the curve $D P$ is an hyperbola.

## Conoids.

236. Def. If a conic revolve about one of its principal axes, the surface generated is called a convid.

If the conic be a circle, the conoid is a sphere.
If the conic be an ellipse, the conoid is an oblate or a prolate spheroid according as the revolution takes place about the conjugate or the transverse axis.

If it be an hyperbola the surface is an hyperboloid of one or two sheets, according as the revolution takes place about the conjugate or transverse axis, and the surface generated by the asymptotes is called the asymptotic cone.

If the conic consist of two intersecting straight lines, the limiting form of an hyperbola, the revolution will be

240 The Oblique Cylinder, the Oblique Cone, about one of the lines bisecting the angles between them, and the conoid will then be a right circular cone.
237. Prop. V. A section of a paraboloid by a plane parallel to the axis is a parabola equal to the generating parabola, and any other section not perpendicular to the axis is an ellipse.

Let $P V N$ be a section parallel to the axis, and take

the plane of the paper perpendicular to the section and cutting it in $V N$.

Take any circular section $D P E$, cutting the section $P V N$ in $P N P^{\prime}$.

Then $P N$ is perpendicular to $D E$,
and

$$
\begin{aligned}
P N^{2} & =D N . N E \\
& =D C^{2}-N C^{2} \\
& =4 A S \cdot A C-4 A S \cdot A n \\
& =4 A S \cdot V N ;
\end{aligned}
$$

therefore the curve $V P$ is a parabola equal to $E A D$.
Again, let $B P F$ be a section not parallel or perpendicular to the axis, but perpendicular to the plane of the paper;

Then, $B N . N F=4 S G . V N, O G$ being the diameter bisecting $B F$;
therefore $\quad P N^{2}: B N . N F:: A S: S G$,
and the curve $B P N$ is an ellipse.
Moreover if the plane $B F$ move parallel to itself, $S G$ is unaltered, and the sections by parallel planes are similar ellipses.

In exactly the same manner, it may be shewn that the oblique sections of spheroids are ellipses, and those of hyperboloids either ellipses or hyperbolas.
238. Prop. VI. The sections of an hyperboloid and its asymptotic cone by a plane are similar curves.

Taking the case of an hyperboloid of two sheets, let $D P F, d P^{\prime} f$, be the sections of the hyperboloid and cone,

$P^{\prime} P N$ the line in which their plane is cut by a circular section $G P K$ or $g P^{\prime} k$.

Through $D$ draw $L D l$ perpendicular to the axis ; then, since $P N^{2}=G N . N K$,
B. C. S.

242 The Oblique Cylinder, the Oblique Cone,
and

$$
P^{\prime} N^{2}=g N . N k,
$$

$$
\begin{aligned}
P^{\prime} N^{2}: d N . N f & :: g N . N k: d N . N f, \\
& :: L D . l D: D d . D f, \\
& :: B C^{2}: C E^{2}
\end{aligned}
$$

if $C E$ be the semidiameter parallel to $D F$;
and $\quad P N^{2}: D N . N F:: G N . N K: D N . N F$

$$
:: B C^{2}: C E^{2} ;
$$

therefore the curves $D P F, d P^{\prime} f$ have their axes in the same ratio, and are similar ellipses.

In the same manner the theorem can be established if the sections be hyperbolic, or if the hyperboloid be of one sheet.
239. Prop. VII. If an hyperboloid of one sheet be cut by a tangent plane of the asymptotic cone, the section will consist of two parallel straight lines.

Let $A Q, A^{\prime} Q^{\prime}$ be a section through the axis, $C N$ the generating line, in the plane $A Q$, along which the tangent

plane touches the cone; and $P N P^{\prime}$ the section with this tangent plane of a circular section $Q P Q^{\prime}$.

Then

$$
\begin{aligned}
P N^{2} & =Q N \cdot N Q^{\prime} \\
& =A C^{2}, \text { Art. (102); }
\end{aligned}
$$

therefore if $B C B^{\prime}$ be the diameter, perpendicular to the plane $C A Q$, of the principal circular section,

$$
P N=B C \text { and } P^{\prime} N=B^{\prime} C
$$

therefore $P B$ and $P^{\prime} B^{\prime}$ are each parallel to $C N$; that is, the section consists of two parallel straight lines.
240. Prop. VIII. The section of an hyperboloid of one sheet by a plane parallel to its axis, and touching the certral circular section, consists of two straight lines.

Let the plane pass through $A$, and be perpendicular to the radius $C A$ of the central section ; fig. Art. (239).

The plane will cut the circular section $Q P Q^{\prime}$ in a line $R L R^{\prime}$, and

$$
R L^{2}=Q L . L Q^{\prime}=Q M^{2}-A C^{2},
$$

if $M$ be the middle point of $Q Q^{\prime}$.
But

$$
Q M^{2}-A C^{2}: C M^{2}:: A C^{2}: B C^{2} ;
$$

therefore

$$
R L: A L:: A C: B C ;
$$

hence it follows that $A R$ is a fixed line ; and similarly $A R^{\prime}$ is also a fixed line.

It will be seen that these lines are parallel to the section of the cone by the plane through the axis perpendicular to $C A$.
241. Prop. IX. If a conoid be cut by a plane, and if spheres be inscribed in the conoid touching the plane, the points of contact of the spheres with the plane will be the foci of the section, and the lines of intersection of the planes of contact with the plane of section will be the directrices.

In order to establish this statement, we shall first demonstrate the following theorem;

If a circle touch a conic in two points, the tangent from any point of the conic to the circle bears a constant ratio to its distance from the chord of contact.

Take the case of an ellipse, the chord of contact being perpendicular to the transverse axis.

If $E M E^{\prime}$ be this chord, the normal $E G$ is the radius of

244 The Oblique Cylinder, the Oblique Cone, the circle, and if $P T$ be a tangent from a point $P$ of the ellipse,

$$
\begin{aligned}
P T^{2} & =P G^{2}-G E^{2} \\
& =P N^{2}+N G^{2}-E M^{2}-M G^{2}
\end{aligned}
$$

But $E M^{2}-P N^{2}: C N^{2}-C M^{2}:: B C^{2}: A C^{2}$, and

$$
C N^{2}-C M^{2}=M N(C M+C N) .
$$

Let the normal at $P$ meet the axis in $G^{\prime}$;
then

$$
N G^{\prime}: C N:: B C^{2}: A C^{2}
$$

and
$M G: C M: B C^{2}: A C^{2}$;
therefore $N G^{\prime}+M G: C N+C M:: B C^{2}: A C^{2}$.
Hence $E M^{2}-P N^{2}=M N\left(N G^{\prime}+M G\right)$.
Also $\quad N G^{2}-M G^{2}=M N(N G+M G)$;
therefore $\quad P T^{2}=M N(N G+M G)-M N\left(N G^{\prime}+M G\right)$

$$
=M N . G G^{\prime} .
$$

But

$$
C G: C M:: S C^{2}: A C^{2}
$$

and $\quad C G^{\prime}: C N:: S C^{2}: A C^{2}$;
therefore $\quad G G^{\prime}: M N:: S C^{2}: A C^{2}$.
Hence $\quad P T^{2}: P L^{2}: S C^{2}: A C^{2}$,
$P L$ being equal to $M N$.
This being established let the figure revolve round the axis $A C$, and let a plane section $a p$ of the conoid, perpendicular to the plane of the paper, touch the sphere at $S$ and cut the plane of contact $E E^{\prime}$ in $l k$.

From a point $p$ of the section let fall the perpendicular $p m$ on the plane $E E^{\prime}$, draw $m k$ perpendicular to $l k$, and join $p k$.

Then $p m: p k$ is a constant ratio.
Also taking the meridian section through $p, p S$ is equal to the tangent from $p$ to the circular section of the sphere, and is therefore in a constant ratio to $p m$;

Hence $S p$ is to $p k$ in a constant ratio, and therefore $S$ is the focus and $k l$ the directrix of the section $a p$.
242. If the curve be a parabola focus $S^{\prime \prime}$, the proof is as follows:

$$
\begin{aligned}
P T^{2} & =P G^{2}-E G^{2} \\
& =P N^{2}+N G^{2}-E M^{2}-M G^{2} \\
& =M N(N G+M G)-4 A S^{\prime} \cdot M N \\
& =M N(N G+M G)-2 M G \cdot M N \\
& =M N^{2} .
\end{aligned}
$$

It will be found that the theorem is also true for an hyperboloid of two sheets, and for an hyperboloid of one sheet, but that in the latter case the constant ratio of $P T$ to $P L$ is not that of $S C$ to $A C$.
243. The geometrical enunciation of the theorem also requires modification in several cases. To illustrate the difficulty, take the paraboloid, and observe that if the

246 The Oblique Cylinder, the Oblique Cone, \&c. normal at $E$ cuts the axis in $G^{Y}$, and if $O$ be the centre of curvature at $A$,

$$
A G>A O
$$

and the radius of the circle is never less than $A O$.
This shews that a circle the radius of which is less than $A O$ cannot be drawn so as to touch the conic in two points.

We may mention one exceptional case in which the theorem takes a simple form.

In general

$$
\begin{aligned}
E G^{2} & =E M^{2}+M G^{2}=4 A S^{\prime}\left(A M+A S^{\prime}\right) \\
& =4 A S^{\prime} \cdot S^{\prime} G .
\end{aligned}
$$

Taking the point $g$ between $S^{\prime}$ and $O$, describe a circle centre $g$ and such that the square on its radius $=4 A S^{\prime \prime} . S^{\prime \prime} g$.

Also take a point $F$ in the axis produced such that $A F=O g ;$
it will then be found that the tangent from $P$ to the circle will be equal to $N F$.

When $g$ coincides with $S^{\prime \prime}$, the circle becomes a point, and

$$
A F=A S^{\prime \prime} ;
$$

we thus fall back on the fundamental definition of a parabola.

It will be found that if the plane section of the conoid pass through $S^{\prime \prime}$, the point $S^{\prime}$ is a focus of the section.

## APPENDIX.

244. If a circle roll on the inside of the circumference of a circle of double its radius, any point in the area of the rolling circle traces out an ellipse.

Let $C$ be the centre of the rolling circle, $E$ the point of contact.

Then, if the circle meet in $Q$ a fixed radius $O A$ of the fixed circle, the angle $E C Q$ is twice the angle $E O A$ and therefore the arcs $E Q, E A$ are equal.

Hence, when the circles touch at $A$, the point $Q$ of the rolling circle coincides with $A$, and the subsequent path of $Q$ is the diameter through $A$.

Let $P$ be a given point in the given radius $C Q$, and $R P N$ perpendicular to $O A$;

Then, $O Q E$ being a right angle, $E Q$ is parallel to $R P$ and therefore $C R=C P$, and $O R$ is constant.

Also

$$
P N: R N:: P Q: O R ;
$$

therefore, the locus of $R$ being a circle, the locus of $P$ is an ellipse, whose axes are as $P Q: O R$.

But $O R$ is clearly the length of one semi-axis, and $P Q$ or $O R^{\prime}$ is therefore the length of the other, $O R, O R^{\prime}$ being equal to $O C+C P$ and $O C-C P$.
245. Properties of the ellipse are deducible from this construction.

Thus, as the circle rolls, the point $E$ is instantaneously at rest, and the motion of $P$ is therefore at right angles to $E P$, i.e. producing $E P$ to $F$, in the direction $F O$.

Therefore, drawing $\boldsymbol{P T}$ parallel to $O F, P \boldsymbol{T}$ is the tangent, and $P F$ the normal.

A circle can be drawn through $E P Q T$ since $E P T$, $E Q T$ are right angles; but the circle through $Q P E$ clearly passes through $R$; therefore the angle ORT is a right angle, and
or

$$
\begin{gathered}
O N: O R:: O R: O T \\
O N . O T=O R^{2}
\end{gathered}
$$

a known property of the tangent.
Again if $P F$ meet $O Q$ in $G$, the angles $P Q G, P F Q$ are equal, being on equal bases $E Q, O Q^{\prime}$;
therefore
or

$$
P G: P Q:: P Q: P F,
$$

a known property of the normal.
246. A given straight line has its ends moreable on two straight lines at right angles to each other; the path of any given point in the moving line is an ellipse.

Let $P$ be the point in the moving line $A B$, and $C$ the middle point of $A B$.

Let the ordinate $N P$, produced if necessary, meet $O C$ in $Q$; then $C Q=C P$ and $O Q$ is equal to $A P$, so that the locus of $Q$ is a circle.

Also

$$
\begin{aligned}
P N: Q N & :: P B: O Q \\
& :: P B: P A ;
\end{aligned}
$$

therefore the locus of $P$ is an ellipse, and its semi-axes are equal to $A P$ and $B P$.
247. The theorem of Art. 244 is at once reducible to this case, for $Q P Q^{\prime}$ being a diameter of the rolling circle is of constant length, and the points $Q$ and $Q^{\prime}$ move along fixed straight lines at right angles to each other; the locus of $P$ is therefore an ellipse of which $Q^{\prime} P$ and $P Q$ are the semi-axes.
248. From this construction also properties of the tangent and normal are deducible.

Complete the rectangle $O A E B$; then, since the directions of motion of $A$ and $B$ are respectively perpendicular to $E A$ and $E B$, the state of motion of the line $A B$ may be represented by supposing that the triangle $E A B$ is turning round the point $\boldsymbol{E}$.

Hence it follows that $E P$ is the normal to the locus of $P$ and that $P T$ perpendicular to $E P$ is the tangent.

Let $O F$ parallel to $P T$ meet $E P$ in $F$; then since a circle can be drawn through $O F B E$,

$$
\text { the angle } P F B=E O B=P B G \text {, }
$$

and the triangles $P G B, P F B$ are similar.
or

$$
\begin{gathered}
P G: P B:: P B: P F, \\
P G . P F=P B^{2},
\end{gathered}
$$

where $P B$ is equal to the semi-conjugate axis; and, similarly, by joining $A F$, it can be shewn that $P g . P F=A P^{2}$, $g$ being the point of intersection of $P G$ and $A O$.

Again, a circle can be drawn round $E Q P B$, and, since $E P T, E B T$ are right angles, $T$ is on this circle, and therefore $T Q E$ is a right angle.

Hence $O Q N$, and $O Q T$ are similar triangles, and
or

$$
\begin{gathered}
O N: O Q: O Q: O T, \\
O N . O T=A P^{3},
\end{gathered}
$$

where $A P$ is equal to the semi-transverse axis.
249. Observing that the circle circumscribing the rectangle passes through $F$, we have

$$
P F \cdot P E=A P \cdot P B ;
$$

hence $P E$ is equal to the semi-diameter conjugate to $O P$.
This suggests another construction for the problem solved in Art. (216).

Thus, if $O P, O D$ be the given semi-conjugate diameters, draw $P F$ perpendicular to $O D$, and in $F P$ produced, take $P E$ equal ta $O D$.

Join $O E$, bisect it in $C$, and take $C Q$ equal to $C P$; then $O A, O B$ drawn parallel and perpendicular to $P Q$, and meeting $C P$ in $A$ and $B$, will be the directions of the axes, and their lengths will be equal to $A P$ and $P B$.
250. If a given triangle $A Q B$ move in its own plane so that the extremities $\mathrm{A}, \mathrm{B}$, of its base AB move on two
fixed straight lines at right angles to each other, the path of the point Q is an ellipse.

If $O$ be the point of intersection of the fixed lines, and $C$ the middle point of $A B$,
the angles $C O B, C B O$ are equal,
so that, as $A B$ slides, the line $C B$, and therefore also the line $C Q$, turns round as fast as $C O$, but in the contrary direction.

Produce $O C$ to $P$, making $C P=C Q$; then the locus of $P$ is a circle radius $O C+C Q$.

There is clearly one position of $A B$ for which the points $O, C$, and $Q$ are in one straight line.

Let $O X$ be this straight line, and let $O C, C Q$, be any other corresponding positions of the lines;
then, if $C E$ is parallel to $O X, C E$ bisects the angle $P C Q$, and, drawing $P Q N$ and $C L$ perpendicular to $O X$,

$$
Q N=C L-P E, \quad P N=C L+P E,
$$

hence

$$
\begin{aligned}
Q N: P N & :: O C-C P: O C+C P \\
& :: O C-C Q: O C+C Q,
\end{aligned}
$$

and $\therefore$ the locus of $Q$ is an ellipse of which the semi-axes are $O C+C Q$ and $O C-C Q$.

## MISCELLANEOUS PROBLEMS.

1. On a plane field the crack of the rifle and the thud of the ball striking the target are heard at the same instant; find the locus of the hearer.
2. $P Q, P^{\prime} Q^{\prime}$ are two focal chords of a parabola, and $P R$, parallel to $P^{\prime} Q^{\prime}$, meets in $R$ the diameter through $Q$; prove that

$$
P Q \cdot P^{\prime} Q^{\prime}=P R^{2} .
$$

3. $C P$ and $C D$ are conjugate semi-diameters of an ellipse; $P Q$ is a chord parallel to one of the axes; shew that $D Q$ is parallel to one of the straight lines which join the ends of the axes.
4. A line cuts two concentric, similar and similarly situated ellipses in $P, Q, q, p$. If the line move parallel to itself, $P Q . Q P$ is constant.
5. If the ordinate $N P$ of a conic be produced so that $N Q=S P$, find the locus of $Q$.
6. If a circle be described passing through any point $P$ of a given hyperbola, and the extremities of the transverse axis, and the ordinate $N P$ be produced to meet the circle in $Q$, the locus of $Q$ is an hyperbola.
7. $P Q$ is one of a series of chords inclined at a constant angle to the diameter $A B$ of a circle; find the locus of the intersection of $A P, B Q$.
8. If from a point $T$ in the director circle of an ellipse, tangents $T P, T P^{\prime}$ be drawn, the line joining $T$ with the intersection of the normals at $P$ and $P^{\prime}$ passes through the centre.
9. The points, in which the tangents at the extremities of the transverse axis of an ellipse are cut by the tangent at any point of the curve, are joined, one with each focus; prove that the point of intersection of the joining lines lies in the normal at the point.
10. Having given a focus, the eccentricity, a point of the curve, and the tangent at the point, shew that in general two
conics can be described. If the eccentricity be less than unity, shew that there are two positions of the tangent for which only one conic can be described, and if the eccentricity be equal to unity, describe the form assumed by one of the parabolas.
11. A parabola is described with its focus at one focus of a given central conic, and touches the conic; prove that its directrix will touch a fixed circle.
12. The extremities of the latera recta of all conics which have a common transverse axis lie on two parabolas.
13. $O P, O Q$ touch a parabola at the points $P, Q$; another line touches the parabola in $R$, and meets $O P, O Q$ in $S, T$; if $V$ be the intersection of the lines $P T, S Q, O, R, V$ are in a straight line.
14. On all parallel chords of a circle a series of isosceles triangles are described, having the same vertical angle, and having their planes perpendicular to the plane of the circle. Find the locus of their vertices; and find what the vertical angle must bs in order that the locus may be a circle.
15. A series of similar ellipses whose major axes are in the same straight line pass through two given points. Prove that the major axes subtend right angles at four fixed points.
16. From the centre of two concentric circles a straight line is drawn to cut them in $P$ and $Q$; through $P$ and $Q$ straight lines are drawn parallel to two given lines at right angles to each other. Shew that the locus of their point of intersection is an ellipse.
17. A circle always passes through a fixed point, and cuts a given straight line at a constant angle, prove that the locus of its centre is an hyperbola.
18. The area of the triangle formed by three tangents to a parabola is equal to one half that of the triangle formed by joining the points of contact.
19. If a parabola touch the sides of a triangle its directrix passes through the orthocentre.
20. $S$ and $H$ being the foci, $P$ a point in the ellipse, if $H P$ be bisected in $L$, and $A L$ be drawn from the vertex cutting $S P$ in $Q$, the locus of $Q$ is an ellipse whose focus is $S$.
21. If the diagonals of a quadrilateral circumscribing an ellipse meet in the centre the quadrilateral is a parallelogram.
22. A. series of ellipses pass through the same point, and have a common focus, and their major axes of the same length; prove that the locus of their centres is a circle. What are the limits of the eccentricities of the ellipses, and what does the ellipse becone at the higher limit?
23. If $S, H$ be the foci of an hyperbola, $L L^{\prime}$ any tangent intercepted between the asymptotes $S L . H L=C L . L L$.
24. Tangents are drawn to an ellipse from a point on a similar and similarly situated concentric ellipse; shew that if $P, Q$ be the points of contact, $A, A^{\prime}$ the ends of the axis of the first ellipse, the loci of the intersections of $A P, A^{\prime} Q$, and of $A Q$, $A^{\prime} P$ are two ellipses similar to the given ellipses.
25. Draw a parabola which shall touch four given straight lines. Under what condition is it possible to describe a parabola touching five given straight lines?
26. A fixed hyperbola is touched by a concentric ellipse. If the curvatures at the point of contact are equal the area of the ellipse is constant.
27. A circle passes through a fixed point, and cuts off equal chords $A B, C D$ from two given parallel straight lines; prove that the envelope of each of the chords $A D, B C$ is a central conic having the fixed point for one focus.
28. Four points $A, B, C, D$, are taken, no three of which lie in a straight line, and joined in every possible way; and with another point as focus four conics are described touching respectively the sides of the triangles $A B C, B C D, C D A, D A B$; prove that the four conics have a common tangent.
29. $P Q$ is any chord of a parabola, cutting the axis in $L$, $R, R^{\prime}$ are the two points in the parabola at which this chord subtends a right angle : if $R R^{\prime}$ be joined, meeting the axis in $L^{\prime}$, $L L^{\prime}$ will be equal to the latus rectum.
30. If the internal and external bisectors of the angle between two tangents to a central conic meet the transverse axis in $G$ and $T$, shew that $C G . C T$ is constant.
31. Three chords of a circle pass through a point on the circumference; with this point as focus and the chords as axes three parabolas are described whose parameters are inversely proportional to the chords; prove that the common tangents to the parabolas, taken two and two, meet in a point,
32. If $P G, p g$, the normals at the ends of a focal chord, intersect in $O$, the straight line through $O$ parallel to $P p$ bisects Gq.
33. With the orthocentre of a triangle as centre are described two ellipses, one circumscribing the triangle and the other touching its sides; prove that these ellipses are similar, and their homologous axes at right angles.
34. An ellipse and a parabola, whose axes are parallel, have the same curvature at a point $P$ and cut one another in $Q$; if the tangent at $P$ meets the axis of the parabola in $T$, prove $P Q$ is equal to four times $P T$.
35. $A B C D$ is a quadrilateral, the angles at $A$ and $C$ being equal; a conic is described about $A B C D$ so as to touch the circumscribing circle of $A B C$ at the point $B$; shew that $B D$ is a diameter of the conic.
36. The volume of a cone cut off by a plane bears a constant ratio to the cube, the edge of which is equal to the minor axis of the section.
37. A tangent to an ellipse at $P$ meets the minor axis in $t$, and $t Q$ is perpendicular to $S P$; prove that $S Q$ is of constant length, and that if $P M$ be the perpendicular on the minor axis, QM will meet the major axis in a fixed point.
38. Describe an ellipse with a given focus touching three given straight lines, no two of which are parallel and on the same side of the focus.
39. Prove that the conic which touches the sides of a triangle, and has its centre at the centre of the nine-point circle, has one focus at the orthocentre, and the other at the centre of the circumscribing circle.
40. From $Q$ the middle point of a chord $P P^{\prime}$ of an ellipse whose focus is $S, Q G$ is drawn perpendicular to $P P^{\prime}$ to meet the major axis in $G$; prove that $2 . S G: S P+S P^{\prime}:: S A: A X$.
41. An ellipse and parabola have the same focus and directrix; tangents are drawn to the ellipse at the extremities of the major axis: shew that the diagonals of the quadrilateral formed
by the four points where these tangents cut the parabola intersect in the common focus, and pass through the extremities of the minor axis of the ellipse.
42. $\Lambda$ straight rod moves in any manner in a plane; prove that, at any instant, the directions of motion of all its particles are tangents to a parabola.
43. If from a point $T$ on the auxiliary circle, two tangents be drawn to an ellipse touching it in $P$ and $Q$, and when produced meeting the circle again in $p, q$; shew that the angles $P S p$ and $Q S q$ are together equal to the supplement of $P T Q$.
44. Tangents at the extremities of a pair of conjugate diameters of an ellipse meet in $T$; prove that $S T, S^{\prime} T$ meet the conjugate diameters in four points which lie on a circle.
45. From the point of intersection of an asymptote and a directrix of an hyperbola a tangent is drawn to the curve, prove that the line joining the point of contact with the focus is parallel to the asymptote.
46. If a string longer than the circumference of an ellipse be always drawn tight by a pencil, the straight portions being tangents to the ellipse, the pencil will trace out a confocal ellipse.
47. $D$ is any point in a rectangular hyperbola from which chords are drawn at right angles to each other to meet the curve. If $P, Q$ be the middle points of these chords, prove that the circle circumscribing the triangle $P Q D$ passes through the centre of the hyperbola.
48. At any point of a conic the chord of curvature through the centre is to the focal chord parallel to the tangent as the major axis is to the diameter through the point.
49. From a point $T$ in the auxiliary circle tangents are drawn to an ellipse, touching it in $P$ and $Q$, and meeting the auxiliary circle again in $p$ and $q$; shew that the angle $p C q$ is equal to the sum of the angles $P S Q$ and $P S^{\prime} Q$.
50. The angle between the focal distance and tangent at any point of an ellipse is half the angle subtended at the focus by the diameter through the point.
51. Tangents to an ellipse, foci $S$ and $H$, at the ends of a focal chord $P H P^{\prime}$ meet the further directrix in $Q, Q^{\prime}$. The parabola, whose focus is $S$, and directrix $P P^{\prime}$, touches $P Q, P^{\prime} Q^{\prime}$, in $Q, Q^{\prime}$; it also touches the normals at $P, P^{\prime}$, and the minor axis, and has for the tangent at its vertex the diameter parallel to $P P^{\prime}$.
52. $S$ is a fixed point, and $E$ a point moving on the arc of a given circle; prove that the envelope of the straight line through $E$ at right angles to $S E$ is a conic.
53. A circle passing through a fixed point $S$ cuts a fixed circle in $P$, and has its centre at $O$; the lines which bisect the angle $S O P$ all touch a conic of which $S$ is a focus.
54. If a chord $R P Q V$ meet the directrices of an ellipse in $R$ and $V$, and the circumference in $P$ and $Q$, then $R P$ and $Q V$ subtend, each at the focus nearer to it, angles of which the sum is equal to the angle between the tangents at $P$ and $Q$.
55. The tangent to an ellipse at $P$ meets the directrix, corresponding to $S$, in $Z$ : through $Z$ a straight line $Z Q R$ is drawn cutting the ellipse in $Q, R$; and the tangents at $Q, R$ intersect (on $S P$ ) in T. Shew that a conic can be described with focus $S$, and directrix $P Z$, to pass through $Q, R$ and $T$; and that $T Z$ will be the tangent at $T$.
56. A sphere is described about the vertex of a right cone as centre; the latera recta of all sections made by tangent planes to the sphere are equal.
57. $T P, T Q$ are tangents to an ellipse at $P$ and $Q$; one circle touches $T P$ at $P$ and meets $T Q$ in $Q$ and $Q^{\prime}$, another touches $T Q$ at $Q$ and meets $T P$ in $P$ and $P^{\prime}$; prove that $P Q^{\prime}$ and $Q P^{\prime}$ are divided in the same ratio by the ellipse.
58. Two tangents are drawn to the same branch of a rectangular hyperbola from an external point; prove that the angles which these tangents subtend at the centre are respectively equal to the angles which they make with the chord of contact.
59. If the normal at a point $P$ of an hyperbola meet the minor axis in $g, P g$ will be to $S g$ in a constant ratio.
B. C. S.
60. A parabola, focus $S$, touches the three sides of a triangle $A B C$, bisecting the base $B C$ in $D$; prove that $A S$ is a fourth proportional to $A D, A B$, and $A C$.
61. An ordinate $N P$ of án ellipse is produced to meet the auxiliary circle in $Q$, and normals to the ellipse and circle at $P$ and $Q$ meet in $R ; R K, R L$ are drawn perpendicular to the axes; prove that $K P L$ is a straight line, and also that $K P=B C$ and $L P=A C$.
62. If the tangent at any point $P$ cut the axes of a conic, produced if necessary, in $T$ and $T^{\prime}$, and if $C$ be the centre of the curve, prove that the area of the triangle $T C T^{\prime \prime}$ varies inversely as the area of the triangle $P C N$, where $P N$ is the ordinate of $P$.
63. The circle of curvature of an ellipse at $P$ passes through the focus $S, S M$ is drawn parallel to the tangent at $P$ to meet the diameter of the ellipse in $M$; shew that it divides this diameter in the ratio of $3: 1$.
64. Prove the following construction for a pair of tangents from any external point $T$ to an ellipse of which the centre is $C$ : join $C T$, let $T P C P^{\prime} T$ a similar and similarly situated ellipse be drawn, of which $C T$ is a diameter, and $P, P^{\prime}$ its points of intersection with the given ellipse; $T P, T P^{\prime}$ will be tangents to the given ellipse.
65. An ellipse and confocal hyperbola intersect in $P$ : prove that an asymptote of the hyperbola passes through the point on the auxiliary circle of the ellipse corresponding to $P$.
66. Through a fixed point a pair of chords of a circle are drawn at right angles: prove that each side of the quadrilateral formed by joining their extremities envelopes a conic of which the fixed point and the centre of the circle are foci.
67. A conic section is circumscribed by a quadrilateral $A B C D: A$ is joined to the points of contact of $C B, C D$; and $C$ to the points of contact of $A B, A D$ : prove that $B D$ is a diagonal of the interior quadrilateral thus formed.
68. Any conic passing through the four points of intersection of two rectangular hyperbolas will be itself a rectangular hyperbola.
69. A focal chord $P S Q$ is drawn to a conic of which $C$ is the centre; the tangents and normals at $P$ and $Q$ intersect in $T$ and $K$ respectively; shew that $S T, S P, S K, S C$ form an harmonic pencil.
70. $P C P^{\prime}$ is any diameter of an ellipse. The tangents at any two points $D$ and $E$ intersect in $F . P E, P^{\prime} D$ intersect in $G$. Shew that $F G$ is parallel to the diameter conjugate to $P C P^{\prime}$.
71. If the common tangent of an ellipse and its circle of curvature at $P$ be bisected by their common chord, prove that

$$
C D^{3}=A C \cdot B C
$$

72. A parabola and hyperbola have the same focus and directrix, and $S P Q$ is a line drawn through the focus $S$ to meet the parabola in $P$, and the nearer branch of the hyperbola in $Q$; prove that $P Q$ varies as the rectangle contained by $S P$ and $S Q$.
73. $R$ is the middle point of a chord $P Q$ of a rectangular hyperbola whose centre is $C$. Through $R, R Q^{\prime}, R P^{\prime}$ are drawn parallel to the tangents at $P$ and $Q$ respectively, meeting $C Q$, $C P$ in $Q^{\prime}, P^{\prime}$. Prove that a circle can be described about $C, P^{\prime}$, $R, Q^{\prime}$.
74. The tangents at two points $Q, Q^{\prime}$ of a parabola muet the tangent at $P$ in $R, R^{\prime}$ respectively, and the diameter through their point of intersection $T$ meets it in $K$; prove that $P R=K R^{\prime}$, and that, if $Q M, Q^{\prime} M^{\prime}, T^{\prime} N$ be the ordinates of $Q, Q^{\prime}, T$ respectively to the diameter through $P, P N$ is a mean proportional between $P M$ and $P M^{\prime}$.
75. Common tangents are drawn to two parabolas, which have a common directrix, and intersect in $P, Q$ : prove that the chords joining the points of contact in each parabola are parallel to $P Q$, and the part of each tangent between its points of contact with the two curves is bisected by $P Q$ produced.
76. An ellipse has its centre on a given hyperbola and touches the asymptotes. The area of the ellipse being always a maximum, prove that its chord of contact with the asymptotes aiways touches a similar hyperbola.
77. A circle and parabola have the same vertex $A$ and a common axis. $B A^{\prime} C$ is the double ordinate of the parabola which touches the circle at $A^{\prime}$, the other extremity of the dia-
meter which passes through $A$; $P P^{\prime}$ any other ordinate of the parabola parallel to this, meeting the axis in $N$ and the chord $A B$ produced in $R$ : shew that the rectangle between $R P$ and $R P^{\prime}$ is proportional to the square on the tangent drawn from $N$ to the circle.
78. If two confocal conics intersect, prove that the centre of curvature of either curve at a point of intersection is the pole of the tangent at that point with regard to the other curve.
79. Tangents are drawn at two points $P, P^{\prime}$ on an ellipse. If any tangent be drawn meeting those at $P, P^{\prime}$ in $R, R^{\prime}$, shew that the line bisecting the angle $R S R^{\prime}$ intersects $R R^{\prime}$ on a fixed tangent to the ellipse. Find the point of contact of this tangent.
80. Having given a focus and two tangents to a conic, shew that the chord of contact passes through a fixed point.
81. Having given a pair of conjugate diameters of an ellipse, $P C P^{\prime}, D C D^{\prime}$, let $P F$ be the perpendicular from $P$ on $C D$, in $P F$ take $P E$ equal to $C D$, bisect $C E$ in $O$, and on $C E$ as diameter describe a circle; prove that PO will meet the circle in two points $Q$ and $R$ such that $C Q, C R$ are the directions of the semiaxes, and $P Q, P R$ their lengths.
82. If from any point $A$ a straight line $A E K$ be drawn parallel to an asymptote of an hyperbola, and meeting the polar of $A$ in $K$ and the curve in $E$, shew that $A E=E K$.
83. The foci of all ellipses which have a common maximum circle of curvature at a fixed point lie on a circle.
84. A straight line is drawn through the angular point $A$ of a triangle $A B C^{\gamma}$ to meet the opposite side in $a$; two points $O, O^{\prime}$ are taken on $A a$, and $C O, C O^{\prime}$ meet $A B$ in $c$ and $c^{\prime}$, and $B O, B O^{\prime}$ meet $C A$ in $b, b^{\prime}$; shew that a conic passing through $a b b^{\prime} c c^{\prime}$ will be touched by $B C$.
85. If $T P, T Q$ are two tangents to a parabola, and any other tangent meets them in $Q$ and $R$, the middle point of $Q R$ describes a straight line.
86. Lines from the centre to the points of contact of two paralled tangents to a rectangular hyperbola and concentric circle make equal angles with either axis of the hyperbola.
87. A line moves between two lines at right angles so as to subtend a right angle and a half at a fixed point on the bisector of the right angle; prove that it touches a rectangular hyperbola.
88. Two cones, whose vertical angles are supplementary, are placed with their vertices coincident and their axes at right angles, and are cut by a plane perpendicular to a common generating line; prove that the directrices of the section of one cone pass through the foci of the section of the other.
89. The normal at a point $P$ of an ellipse meets the curve again in $P^{\prime}$, and through $O$, the centre of curvature at $P$, the chord $Q O Q^{\prime}$ is drawn at right angles to $P P^{\prime}$; prove that

$$
Q O . O Q^{\prime}: P O . O P^{\prime}:: 2 . P O: P P^{\prime} .
$$

90. From an external point $T$, tangents are drawn to an ellipse, the point of contact being on the same side of the major axis. If the focal distances of these points intersect in $M$ and $N, T M, T N$ are tangents to a confocal hyperbola, which passes through $M$ and $N$.
91. A point moves in a plane so that the sum or difference of its distances from two fixed points, one in the given plane and the other external to $i t$, is constant. It will describe a conic, the section of a right cone whose vertex is the given external point.
92. $Q R$, touching the ellipse at $P$, is one side of the parallelogram formed by tangents at the ends of conjugate diameters; if the normal at $P$ meet the axes in $G$ and $g$, prove that $Q G$ and $R g$ are at right angles.
93. If $P P^{\prime}$ be a double ordinate of an ellipse, and if the normal at $P$ meet $C P^{\prime}$ in $O$, prove that the locus of $O$ is a similar ellipse, and that its axis is to the axis of the given ellipse in the ratio

$$
A C^{2}-B C^{2}: A C^{2}+B C^{2}
$$

94. If $S Y, H Z$ be focal perpendiculars on the tangent at $P$ of an ellipse, and $S Y^{\prime}, H Z^{\prime}$ perpendiculars on the tangents from $P$ to a confocal ellipse, prove that the rectangle contained by $Y Y^{\prime}, Z Z^{\prime}$, is equal to the difference of the squares on the semiaxes.
95. If from any point $P$ of an hyperbola perpendiculars $P E, P F$ be let fall on the asymptotes, the centre of the circle circumscribing the triangle $P E F$ is on a fixed hyperbola.
96. A chord of a conic whose pole is $T$ meets the directrices in $R$ and $R^{\prime}$; if $S R$ and $S R^{\prime}$ meet in $Q$, prove that the minor axis bisects $T Q$.
97. On a parabola, whose focus is $S$, three points $Q, P, Q^{\prime}$ are taken such that the angles $P S Q, P S Q^{\prime}$ are equal; the tangent at $P$ meets the tangents at $Q, Q^{\prime}$ in $T, T^{\prime \prime}$ : shew that $T Q: T^{\prime} Q^{\prime}:: S Q: S Q^{\prime}$.
98. If from any point $P$ of a parabola perpendiculars $P N$, $P L$ are let fall on the axis and the tangent at the vertex, the line $L N$ always touches another parabola.
99. $P Q$ is any diameter of a section of a cone whose vertex is $V$; prove that $V P+V Q$ is constant.
100. From a fixed point $O$ are let fall perpendiculars $O Y$, $O Z$ on the tangent and normal at any point $P$ of a curve; and the straight line joining the feet of these perpendiculars passes through another fixed point $C$; prove that the curve is one of a system of confocal conics.
101. If the axes of two parabolas are in the same direction their common chord bisects their common tangents.
102. If a chord $P Q$, of a parabola, whose pole is $T$, cut the directrix in $F$, the tangents from $F$ bisect the angle $P F T$.
103. A circle is described touching the asymptotes of an hyperbola and having its centre at the focus. A tangent to this circle cuts the directrix in $F$, and has its pole with regard to the hyperbola at $T$. Prove that $T F$ touches the circle.
104. Two conics have a common focus: their corresponding directrices will intersect on their common chord, at a point whose focal distance is at right angles to that of the intersection of their common tangents. Also the parts into which either common tangent is divided by their common chord will subtend equal angles at the common focus.

If the conics are parabolas, the inclination of their azes will be the angle subtended by the common tangent at the common focus.
105. Prove that a chord of a circle which subtends a right angle at a fixed point always touches a conic, whose focus is at that point.
106. Find the position of the normal chord which cuts off from a parabola the least segment.
107. A system of conics have a common focus $S$ and a common directrix corresponding to $S$. A fixed straight line through $S$ intersects the conics, and at the points of intersection normals are drawn. Prove that these normals are all tangents to a parabola.
108. From the point in which the tangent at any point $P$ of an hyperbola meets either asymptote perpendiculars $P M, P N$ are let fall upon the axes. Prove that $M N$ passes through $P$.
109. If two parabolas whose latera recta have a constant ratio, and whose foci are two given points $S, S^{\prime}$ have a contact of the second order at $P$, the locus of $P$ is a circle.
110. In the construction of Art. 216, prove that $C K^{\prime}$ and $C K$ are respectively equal to the sum and difference of the semiaxes.
111. If the diagonals of a quadrilateral circumscribing a conic intersect in a focus, they are at right angles to one another, and the third diagonal is the corresponding directrix.
112. Given a tangent to an ellipse, its point of contact, and the director circle, construct the ellipse.
113. If the tangent at a point $P$ of an ellipse meet the auxiliary circle in $Q^{\prime}, R^{\prime}$, and if $Q, R$ be the corresponding points on the ellipse, the tangents at $Q$ and $R$ pass through the point $P^{\prime}$ on the auxiliary circle corresponding to $P$.
114. If two ellipses have one common focus $S$ and equal major axes, and if one ellipse revolves in its own plane about $S$, the chord of intersection envelopes a conic confocal with the fixed ellipse.
115. If a rectangular hyperbola be intersected by a circle of any radius whose centre is at a fixed point on one of the axes of the curve, the lines joining the points of intersection are. either parallel to an axis, or tangents to a fixed parabola.
116. $C P, C D$ are semi-conjugate diameters of an ellipse; if the circles of curvature at $P$ and $D$ meet the curve again in $Q$ and $R, Q D$ is parallel to $P R$.
117. The tangent at the point $P$ of an hyperbola meets the directrix in $Q$; another point $R$ is taken on the directrix such that $Q R$ subtends at the focus an angle equal to that between the transverse axis and the asymptote; prove that $R P$ envelopes a parabola.
118. The tangent at any point $P$ of an ellipse meets the axis minor in $T$ and the focal distances $S P, H P$ meet it in $R, r$. Also $S T, H T$, produced if necessary, meet the normal at $P$ in $Q, q$, respectively. Prove that $Q r$ and $q R$ are parallel to the axis major.
119. Two points describe the circumference of an ellipse, with velocities which are to one another in the ratio of the squares on the diameters parallel to their respective directions of motion. Prove that the locus of the point of intersection of their directions of motion will be an ellipse, confocal with the given one.
120. If $A A^{\prime}$ be the axis major of an elliptic section of a cone, vertex $V$, and if $A G, A^{\prime} G^{\prime}$ perpendicular to $A V, A^{\prime} V$ meet the axis of the cone in $G$ and $G^{\prime}$, and $G O, G^{\prime} O^{\prime}$ be the perpendiculars let fall on $A A^{\prime}$, prove that $O$ and $O^{\prime}$ are the centres of curvature at $A$ and $A^{\prime}$.
121. By help of the geometry of the cone, or otherwise, prove that the sum of the tangents from any point of an ellipse to the circles of curvature at the vertices is constant.
122. If two tangents be drawn to a section of a cone, and from their intersection two straight lines be drawn to the points where the tangent plane to the cone through one of the tangents touches the focal spheres, prove that the angle contained by these lines is equal to the angle between the tangents.
123. A parabola touches the three lines $C B, C A, A B$ in $P, Q, R$, and through $R$ a line parallel to the axis meets $R Q$ in $E$; shew that $A B E C$ is a parallelogram.
124. If a conic be inscribed in a quadrilateral, shew that the locus of its centre is a straight line.

Shew also that this line passes through the middle points of the diagonals.
125. If two circles be inscribed in a conic, and tangents be drawn to the circles from any point in the conic, the sum or difference of these tangents is constant, according as the point does or does not lie between the two chords of contact.
126. If $C P, C D$ are conjugate semi-diameters and if through $C$ is drawn a line parallel to either focal distance of $P$, the perpendicular from $D$ upon this line will be equal to half the minor axis.
127. The area of the parallelogram formed by the tangents at the ends of any pair of diameters of a central conic varies inversely as the area of the parallelogram formed by joining the points of contact.
128. Two tangents to an hyperbola from $T$ meet the directrix in $F$ and $F^{\prime}$; prove that the circle, centre $T$, which touches $S F, S F^{\prime}$, meets the directrix in two points the radii to which from the point $T$ are parallel to the asymptotes.
129. If $T$ is the pole of a chord of a conic, and $F$ the intersection of the chord $Q q$ with the directrix, $T S F$ is a right angle.
130. The polar of the middle point of a normal chord of a parabola meets the focal vector to the point of concourse of the chord with the directrix on the normal at the further end of the chord.
131. Shew how to draw through a given point a plane which will have the given point for (1) focus, (2) centre, (3) vertex, of the section it makes of a given right circular cone: noticing any limitations in the position of the point which may be necessary.
132. If two sections of a right circular cone have a common directrix, the latera recta are in the ratio of their eccentricities.

## GRAMMAR-SCHOOL CLASSICS.

A Series of Greek and Latin Authors, with English Notes. Fcap. 8vo.
Cæsar : De Bello Gallico. By George Long, M.A. 4s.
__ Books I.-III. For Junior Classes. By G. Long, M.A. 1s. $6 d$.
——Books IV. and V. 1s. 6d. Books VI. and VII., 1s. 6 da.

- Books I., II., and III., with Vocabulary, 1s. 6d. each.

Catullus, Tibullus, and Propertius. Selected Poems. With Life. By Rev. A. H. Wratislaw. 2s. 6 d.
Cicero: De Senectute, De Amicitia, and Select Epistles. By George Long, M.A. 3s.
Cornelius Nepos. By Rev. J. F. Macmichael. $2 s$.
Homer: Iliad. Books I.-XII. By F. A. Paley, M.A., LL.D. 4s. 6d. Also in 2 parts, 2s. 6d. each.
Horace: With Life. By A. J. Macleane, M.A. 3s. $6 d$. In 2 parts, 2s. each. Odes, Book I., with Vocabulary, 1s. 6 d.
Juvenal: Sixteen Satires. By H. Prior, M.A. 3s $6 d$.
Martial : Select Epigrams. With Life. By F.A. Paley, M.A.,LL.D. 4s. 6d.
Ovid : the Fasti. By F. A. Paley, M.A., LL.D. 3s. 6d. Books Iand II., 18. 6d. Books III. and IV., 1s. 6d. Books V. and VI,, 1s. 6d.
Sallust: Catilina and Jugurtha. With Life. By G. Long, M.A. and J. G. Frazer. 3s. 6d., or separately, 2s. each.
Tacitus: Germania and Agricola. By Rev. P. Frost. 2s. 6d.
Virgil : Bucolics, Georgics, and Eneid, Books I.-IV. Abridged from Professor Conington's Edition. 4s. 6d.-TEneid, Books V.-XIIL., 4s. 6 d. Also in 9 separate Volumes, as follows, 1s. 6d. each:-Bucolics-Georgics, I. and II.-Georgics, III. and IV.-EEneid, I. and II.-III. and IV.-V. and VI.-VII. and VIII.-IX. and X.-and XI. and XII. Eneid, Book I., with Vocabulary, 18. 6 d.

Xenophon: The Anabasis. With Life. By Rev. J.F. Macmichael. 3s. 6 . Also in 4 separate volumes, 1s. $6 d$. each:-Book I. (with Life, Introduction, Itinerary, and Three Maps)-Books II. and III.-IV. and V. -VI. and VII.

The Cyropædia. By G. M. Gorham, M.A. 3s. 6d. Books I. and II., 1s. 6d.-Books V. and VI., 18. $6 d$.

Memorabilia. By Percival Frost, M.A. 38.
A Grammar School Atlas of Classical Geography, containing Ten selected Maps. Imperial 8ro. 3s.

## Uniform with the Series.

The New Testament, in Greek. With English Notes, \&c. By Rev. J. F. Macmichael. 4s. 6d. The Four Gospels and the Acts, separately. Sewed, 6d. each.

## CAMBRIDGE GREEK AND LATIN TEXTS.

Aeschylus. By F. A. Paley, M.A., LL.D. 2s.
Cæsar: De Bello Gallico. By G. Long, M.A. $1 s .6 d$.
Cicero: De Senectute et De Amicitia, et Epistolæ Selectæ. By G. Long, M.A. 1s. 6 d.
Ciceronis Orationes. In Verrem. By G. Long, M.A. $2 s .6 \mathrm{~d}$. Euripides. By F. A. Paley, M.A., LL.D. 3 vols. 2s. each. Herodotus. By J. G. Blakesley, B.D. 2 vols. $5 s$.
Homeri Ilias. I.-XII. By F. A. Paley, M.A., LL.D. 1s. $6 d$. Horatius. By A. J. Macleane, M.A. 1s. 6d.
Juvenal et Persius. By A. J. Macleane, M.A. 1s. 6d. Lucretius. By H. A. J. Munro, M.A. 2s.
Sallusti Crispi Catilina et Jugurtha. By G. Long, M.A. 1s. 6d. Sophocles. By F. A. Paley, M.A., LL.D. $2 s .6 d$.
Terenti Comœdiæ. By W. Wagner, Ph.D. 2s.
Thucydides. By J. G. Donaldson, D.D. 2 vols. $4 s$.
Virgilius. By J. Conington, M.A. $2 s$.
Xenophontis Expeditio Cyri. By J. F. Macmichael, B.A. 1s. 6d. Novum Testamentum Græce. By F. H. Scrivener, M.A., D.C.L. 4s. 6d. An edition, with wide margin for notes, half bound, 12s. Editio Major, with additional Readings and References. 7s. 6d. (See page 15.)

## CAMBRIDGE TEXTS WITH NOTES.

A Selection of the most usually read of the Greek and Latin Authors, Annotated for Schools. Edited by well-known Classical Scholars. Fcap. 8vo. 1s. 6d. each, with exceptions.
'Dr. Paley's vast learning and keen appreciation of the difficalties of loginners make his school editions as valuable as they are popular. In many respects he sets a brilliant example to younger scholars.' -Athenoum.
'We hold in high value these handy Cambridge texts with Notes.'Saturday Review.

Aeschylus. Prometheus Vinctus.-Septem contra Thebas.-Aga-memnon.-Persae.-Eumenides.-Choephoroe. By F.A. Paley, M.A., LL.D. Euripides. Alcestis.-Medea.-Hippolytus.-Hecuba. - Bacchae. -Ion. 2s.-Orestes.-Phoenissae.-Troades.-Hercules Furens.-Andro-mache.-Iphigenia in Tauris.-Supplices. By F. A. Paley, M.A., LL.D. Homer. Iliad. Book I. By F. A. Paley, M.A., LL.D. $1 s$. Sophocles. Oedipus Tyrannus. -Oedipus Coloneus. - Antigone. -Electra.-Ajax. By F. A. Paley, M.A., LL.D.
Xenophon. Anabasis. In 6 vols. By J. E. Melhuish, M.A., Assistant Classical Master at St. Paul's School.
—— Hellenics, Book I. By L. D. Dowdall, M.A., B.D. $2 s$. Hellenics, Book II. By L. D. Dowdall, M.A., B.D. 2s.
Cicero. De Senectute, De Amicitia, and Epistolæ Selectæ. By G. Long, M.A.

Ovid. Fasti. By F. A. Paley, M.A., LL.D. In 3 vols., 2 books in each. 28. each rol.

Ovid. Selections. Amores, Tristia, Heroides, Metamorphoses. By A. J. Macleane, M.A.
Terence. Andria.-Hauton Timorumenos.-Phormio.-Adelphoe. By Professor Wagner, Ph.D.
Virgil. Professor Conington's edition, abridged in 12 vols. 'The handiest as well as the soundest of modern editions.'

Saturday Review.

## PUBLIC SCHOOL SERIES.

A Series of ClassicalTexts, annotated by well-known Scholars. Cr. $8 v o$. Aristophanes. The Peace. By F. A. Paley, M.A., LL.D. 4s. 6 d . —— The Acharnians. By F. A. Paley, M.A., LL.D. 4s. $6 d$.

- The Frogs. By F. A. Paley, M.A., LL.D. 4s. 6d.

Cicero. The Letters to Atticus. Bk. I. By A. Pretor, M.A. 3rd Edition. 4s. $6 d$.
Demosthenes de Falsa Legatione. By R. Shilleto, M.A. 7th Edition. 6s.
—The Law of Leptines. By B. W. Beatson, M.A. 3rd Edition. 3s. $6 d$.
Livy. Book XXI. Edited, with Introduction, Notes, and Maps, by the Rev. L. D. Dowdall, M.A., B.D. 3s. 63.
——Book XXII. Edited, \&c., by Rev. L. D. Dowdali, M.A., B.D. 3 s. 6 d.

Plato. The Apology of Socrates and Crito. By W. Wagner, Ph.D. 12th Edition. 3s. 6d. Cheap Edition, limp cloth, 2s. 6 d.

- The Phædo. 9th Edition. By W. Wagner, Ph.D. 5s. 6d.
—— The Protagoras. 7th Edition. By W. Wayte, M.A. 4s. 6d. The Euthyphro. 3rd Edition. By G. H. Wells, M.A. 38.
—— The Euthydemus. By G. H. Wells, M.A. 4s.
——The Republic. Books I. \& II. By G. H. Wells, M.A. 3rd Edition. 5s. 6 d.
Plautus. The Aulularia. By W. Wagner, Ph.D. 5th Edition. 4s. 6d.
—— The Trinummus. By W. Wagner,Ph.D. 5th Edition. 4s. 6d.
—— The Menaechmei. By W. Wagner, Ph.D. 2nd Edit. 4s. 6d. The Mostellaria. By Prof. E. A. Sonnenschein. 5s.
Sophocles. The Trachiniae. By A. Pretor. M.A. 4s. 6d.
-The Oedipus Tyrannus. By B. H. Kennedy, D.D. 5s.

Euclid. Exercises on Euclid and in Modern Geometry. By J. McDowell, M.A. 4th Edition. 6s.

Elementary Trigonometry. By J. M. Dyer, M.A., and Rev. R. H. Whitcombe, M.A., Assistant Masters, Eton College. 2nd Edit. 4s. 6d.

Trigonometry. Plane. By Rev.'T.Vyvyan, M.A. 3rd Edit. 3s. $6 d$.
Geometrical Conic Sections. By H. G. Willis, M.A. 5s.
Conics. The Elementary Geometry of. 7th Edition, revised and enlarged. By C. Taylor, D.D. 4s. $6 d$.
Solid Geometry. By W. S. Aldis, M.A. 4th Edit. revised. 6s.
Geometrical Optics. By W. S. Aldis, M.A. 3rd Edition, 4 s .
Rigid Dynamics. By W. S. Aldis, M.A. $4 s$.
Eliementary Dynamics. By W.Garnett, M.A.,D.C.L. 5th Ed. 6 s.
Dynamics. A Treatise on. By W. H. Besant, Sc.D., F.R.S. 2nd Edition. 7s. 6 d.
Heat. An Elementary Treatise. By W. Garnett, M.A., D.C.L. 5th Edition, revised and enlarged. 4s. 6d.
Elementary Physics. Examples in. By W. Gallatly, M.A. 4s.

Elementary Hydrostatics. By W. H. Besant, Sc.D., F.R.S. 15th Edition, rewritten. Crown 8vo. 4s. 6d. Key 5s. net.
Hydromechanics. By W. H. Besant, Sc.D., F.R.S. 5th Edition. Part I. Hydrostatics. 5s.
Mathematical Examples. By J. M. Dyer, M.A., Eton College, and R. Prowde Smith, M.A., Cheltenham College. 6s.
Mechanics. Problems in Elementary. By W. Walton, M.A. $6 s$. Notes on Roulettes and Glissettes. By W. H. Besant, Sc.D., F.R.S. 2nd Edition, enlarged. Crown 8vo. 5s.

## CAMBRIDGE SCHOOL AND COLLEGE TEXT-BOOKS.

A Series of Elementary Treatises for the use of Students.
Arithmetic. By Rev.C.Elsee, M.A. Fcap. 8vo. 14th Edit. 3s.6d. __ By A. Wrigley, M.A. 3s. 6d.

A Progressive Course of Examples. With Answers. By J. Watson, M.A. 7th Edition, revised. By W. P. Goudie, B.A. 2s.6d. Algebra. By the Rev. C. Elsee, M.A. 8th Edit. 4s.
—— Progressive Course of Examples. By Rev. W. F. M'Michael, M.A., and R. Prowde Smith, M.A. 4th Edition. 3s. 6d. With Answers. 4s. 6 d .
Plane Astronomy, An Introduction to. By P. T. Main, M.A. 6th Edition, revised. 4s.
Conic Sections treated Geometrically. By W. H. Besant, Sc.D. 8th Edition. 4s. 6d. Solution to the Examples. 4s.

Enuaciations and Figures Separately. $1 s$.
Statics, Elementary. By Rev. H. Goodwin, D.D. 2nd Edit. 3s. Mensuration, An Elementary Treatise on. By B.T.Moore, M.A. 3s.6d.
Newton's Principia, The First Three Sections of, with an Appendix; and the Ninth and Eleventh Sections. By J. H. Evans, M.A. 5th Edition, by P. T. Main, M.A. 4s.
Analytical Geometry for Schools. By T. G.Vyvyan. 5th Edit. 4s.6id. Greek Testament, Companion to the. By A. C. Barrett, M.A. 5th Edition, revised. Fcap. 8vo. 5s.
Book of Common Prayer, An Historical and Explanatory Treatise on the. By W. G. Humphry, B.D. 6th Edition. Fcap. 8vo. 2s. 6d.
Music, Text-book of. By Professor H. C. Banister. 15th Edition, revised. 5 s .
——Concise History of. By Rev. H. G. Bonavia Hunt, Mus. Doc. Dublin. 12th Edition, revised. 3s. 6 d .
ARITHMETIC. (See also the two foregoing Series.)
Elementary Arithmetic. By Charles Pendlebury, M.A., Senior Mathematical Master, St. Paul's School; and W. S. Beard, F.R.G.S., Assistant Master, Christ's Hospital. With 2500 Examples, Written and Oral. Crown 8vo. 1s. 6d. With or without Answers.
Arithmetic, Examination Papers in. Consisting of 140 papers, each containing 7 questions. 357 more difficult problems follow. A collection of recent Public Examination Papers are appended. By C. Pendlebury, M.A. 2s. 6d. Key, for Masters only, 5 s .
Graduated Exercises in Addition (Simple and Compound). By W. S. Beard, C. S. Department Rochester Mathematical School. 1s. For Candidates for Commercial Certificates and Civil Service Exams.

## BOOK-KEEPING.

Book-keeping Papers, set at various Public Examinations. Collected and Written by J. T. Medhurst, Lecturer on Book-keeping in the City of London College. 2nd Edition. 3s.
A Text-Book of the Principles and Practice of Book-keeping. By Professor A. W. Thomson, B.Sc., Royal Agricultaral College, Cirencester. Crown 8vo. 5 s.
Double Entry Elucidated. By B. W. Foster. 14th edition. Fcap. 4to. 3s. 6d.
A New Manual of Book-keeping, combining the Theory and Practice, with Specimens of a set of Books. By Phillip Crellin, Accountant. Crown 8vo. 3s. 6d.
Book-keeping for Teachers and Pupils. By Phillip Crellin. Crown 8vo. 1s. 6d. Key, 2s. net.

## GEOMETRY AND EUCLID.

Euclid. Books I.-VI. and part of XI. A New Translation. By H. Deighton. (See p.8.)

- The Definitions of, with Explanations and Exercises, and an Appendix of Exercises on the First Book. By R. Webb, M.A. Crown 8vo. 1s. $6 d$.
—— Book I. With Notes and Exercises for the use of Preparatory Schools, \&c. By Braithwaite Arnett, M.A. 8vo. 4s. 6d.

The First Two Books explained to Beginners. By C. P. Mason, B.A. 2nd Edition. Fcap. 8vo. 2s. $6 d$.
The Enunciations and Figures to Euclid's Elements. By Rev. J. Brasse, D.D. New Edition. Feap. 8vo. 1s. Without the Figures, 6d.

Exercises on Euclid. By J. McDowell, M.A. (See p. 8.)
Mensuration. By B. T. Moore, M.A. 3s. 6d. (See p. 9.)
Geometrical Conic Sections. By H. G. Willis, M.A. (See p. 8.)
Geometrical Conic Sections. By W. H. Besant, Sc.D. (See p. 9.)
Elementary Geometry of Conics. By C. Taylor, D.D. (See p. 8.)
An Introduction to Ancient and Modern Geometry of Conics. By C. Taylor, D.D., Master of St. John's Coll., Camb. 8vo. 15s.
An Introduction to Analytical Plane Geometry. By W. P. Turnbull, M.A. 8vo. 12s.
Problems on the Principles of Plane Co-ordinate Geometry. By W. Walton, M.A. 8vo. 16 s.
Trilinear Co-ordinates, and Modern Analytical Geometry of Two Dimensions. By W. A. Whitworth, M.A. 8vo. 16s.
An Elementary Treatise on Solid Geometry. By W. S. Aldis, M.A. 4th Edition revised. Cr. 8vo. 6s.

Elliptic Functions, Elementary Treatise on. ByA. Cayley, D.Sc. Demy 8vo.
[New Edition Preparing.

## TRIGONOMETRY.

Trigonometry. By Rev. T. G. Vyvyan. 3s. 6d. (See p. 8.)
Trigonometry, Elementary. By J. M. Dyer, M.A., and Rev. R. H. Whitcombe, M.A., $\Lambda$ sst. Masters, Eton College. 4s. 6d. (See p. 8.)
Trigonometry, Examination Papers in. By G. H. Ward, M.A., Assistant Master at St. Paul's School. Crown 8vo. 2s. 6d.

## MECHANICS \& NATURAL PHILOSOPHY.

Statics, Elementary. By H. Goodwin, D.D. Fcap. 8vo. 2nd Edition. 3s.
Dynamics, A Treatise on Elementary. By W. Garnett, M.A., D.O.L. 5th Edition. Crown 8 vo . 6 s.

Dynamics, Rigid. By W. S. Aldis, M.A. 4s.
Dynamics, A Treatise on. By W.H. Besant, Sc.D.,F.R.S. 7s. $6 d$.
Elementary Mechanics, Problems in. By W. Walton, M.A. New Edition. Crown 8vo. 6 s.
Theoretical Mechanics, Problems in. By W. Walton, M.A. 3rd Edition. Demy 8vo. 16 s .
Structural Mechanics. By R. M. Parkinson, Assoc. M.I.C.E.. Crown 8vo. 4s. 6 d .
Elementary Mechanics. Stages I. and II. By J. C. Horobin, B.A. 1s. 6d. each.
Theoretical Mechanics. Division I. (for Science and Art Ex-aminations). By J. C. Horobin, B.A. Crown 8vo. 2 s .6 d .
Hydrostatics. By W.H.Besant, Sc.D. Cr. 8vo. 15th Edit. 4s. 6d. Hydromechanics, A Treatise on. By W. H. Besant, Sc.D., F.R.S. 8vo. 5th Edition, revised. Part I. Hydrostatics. 5 s .
Hydrodynamics, A Treatise on. Vol. I., 10s. 6d.; Vol. II., 12s. $6 d$. A. B. Baseet, M.A., F.R.S.

Hydrodynamics and Sound, An Elementary Treatise on. ByA. B. Basset, M.A., F.R.S. Demy 8vo. 7s. 6 d.

Physical Optics, A Treatise on. By A. B. Basset, M.A., F.R.S. Demy 8ro. 16 s.
Optics, Geometrical. By W. S. Aldis, M.A. Crown 8vo. 3rd Edition. 4s.
Double Refraction, A Chapter on Fresnel's Theory of. By W. S. Aldis, M.A. 8 ro. 2 s .
Roulettes and Glissettes. By W. H. Besant, Sc.D., F.R.S. 2nd Edition, 5 s.
Heat, An Elementary Treatise on. By W. Garnett, M.A., D.C.L. Crown 8vo. 5th Edition. 4s. 6 d .
Elementary Physics, Examples and Examination Papers in. By W. Gallatly, M.A. 4 s.

Newton's Principia, The First Three Sections of, with an Appendix; and the Ninth and Eleventh Sections. By J. H. Evans, M.A.' 5th Edition. Edited by P. T. Main, M.A. 4s.
Astronomy, An Introduction to Plane. By P. T. Main, M.A. Fcap. 8vo. cloth. 6th Edition. 4s.
Mathematical Examples. Pure and Mixed. By J. M. Dyer, M.A., and R. Prowde Smith, M.A. 6 s.
Pure Mathematics and Natural Philosophy, A Compendium of Facts and Formule in. By G. R. Smalley. 2nd Edition, revised by J. McDowell, M.A. Fcap. 8vo. 2 s .

Elementary Course of Mathematics. By H. Goodwin, D.D. 6th Edition. 8vo. 16 s .
A Collection of Examples and Problems in Arithmetic, Algebra, Geometry, Logarithms, Trigonometry, Conic Sections, Mechanicso. de., with Answers. By Rev. A. Wrigley. 20th Thousand. 8s. 6d Key. 10s. 6d.

## FOREIGN CLASSICS.

A Series for use in Schools, with English Notes, grammatical and explanatory, and renderinas of difficult idiomatic expressions. Fcap. 8vo.
'Schillers's Wallenstein. By Dr. A. Buchheim. 6th Edit. 5 s. Or the Lager and Piccolomini, 2s. 6d. Wallenstein's Tod, 2s. 6d.
__ Maid of Orleans. By Dr. W. Wagner. 3rd Edit. 1s. $6 d$. —— Maria Stuart. By V. Kastner. 3rd Edition. 18. 6d.
Goethe's Hermann und Dorothea. By E. Bell, M.A., and E. Wölfel. New Edition, Revised. 1s. 6d.
-German Ballads, from Uhland, Goethe, and Schiller. By C. L. Bielefeld. 5th Edition. 1s. $6 d$.
Charles XII., par Voltaire. By L. Direy. 7th Edition. 1s. 6d.
Aventures de Télémaque, par Fénelon. By C. J. Delille. 4th Edition. 2s. $6 d$.
